My reference above demonstrates that rho is a scalar, but is derived from a magnitude and a phase (explicitly stated in polar notation). This reference being an engineering piece rather than an academic exercise has omitted discussion as to the limits over which theta are allowed - hence the lack of discussion in regard to appearances of the absolute operator in other works.

Hello,
I have an MFJ-259B swr analyzer that tells me all sort of things about my antenna system. Also have an earlier version analyzer that will only give the impedance of the system and the swr. I imagine both instruments have the same kind of measurement bridges in the business end, the 259B has lots more calculating power. Does anyone know how to get R+/-jX indirectly if only the impedance and swr are know? Maybe using a Smith chart normalized to 50 ohms? Also, the cheaper analyzer must only measure Z and get swr from that, but looking at a Smith chart there are infinite swrs from 50 ohms inductive reactance to 50 capacitive reactance. How does it know which one is correct? Thanks for any answers.

You know Z but R and X are unknown. You know SWR but R and X are unknown.
That's two independent equations and two unknowns. Solving for R and X
just involves some messy algebra. It could even be done using a Smith
Chart. I would assume that someone somewhere has already done it. Can
Hamcalc do that? Reg, can any of your software do that?

3071. Re: Another swr question?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-13 22:02:55 UTC
From: Larry Benko <benko@aztek-eng.com>
Message-ID: <3A89AF0F.47C2B87D@aztek-eng.com>
Source record: 170345

SWR = (1 + rho) / (1 - rho)
rho = (sqrt((R + Zo)^2 + X^2)) / (sqrt((R - Zo)^2 + X^2))
Z = sqrt(R^2 + X^2)

Z0 = 50ohms (reference impedance)

Substitute for rho in the SWR equation.
Now you have SWR is a function of R and X
and Z is a function of R and X.

Cecil is correct, 2 equations in 2 unknowns however the solution
is not all that easy.

If the paint is conductive I think there would be an effect. If the coating is thick enough to make a nearly constant plating effect it would be much the same as using a copper pipe as your radome. This would act as the antenna in effect and the inner real antenna would be shielded from having any effect. I wouldn't want anything overly conductive painted on a radome. Probably not a solid vertical either as the antenna metal probably has a low resistance than the paint. I'd want a paint that was invisible to rf. MK

Simplifying a bit this becomes (assuming I made no mistakes)

R = [(Z0^2+Z^2)/Z0] [SWR/(1+SWR^2)]
X^2 = Z^2-R^2

which shows that you can get the magnitude of the reactance X but not its sign from these measurements. That is changing from inductive to capacitive reactance would neither change the SWR or the magnitude of the impedance. In principle you could add a small inductance in series or a small capacitance in parallel with the antenna and see how X changes to get the sign. Looking at a graph may help to estimate the error propagation which may be large. I have a vague recollection that QST had a chart for this conversion several years ago in hints and kinks.

Thanks Cecil and Larry,
I had decided it would be simultaneous equations, but did not know where to find eq. for rho till Larry filled me in. Some number crunching, but not impossible. Was thinking the less expensive analyzers (Vectronics 584B-$150) would have more utility if there were methods for indirectly computing R+/-jX. Still wondering if the Smith Chart can do it? Once again thanks.

Paul, VK3DDU wrote:
"The feed should taper from 2 inches?"

300 ohms is about as low as it is practical to go because the spacing gets so close (0.5 in.). But there is 300-ohm TV gear.

20 inches is the spacing for wire lines with 750 ohm impedance. It`s a high transmission line impedance. It`s handled by tapping the rhombic where it is 20 inches between opposite sides. symmetrically, of course.

At 4 wavelengths per side for your rhombic, you should have about 6 feet of wire in each half of the antenna. I don`t know your design, but the rhombic probably ends up being about twice as long as it is wide. Don`t fret if it isn`t. There are many designs and they could all work well.

Insulators can be used to shorten the wires in the driven end of the rhombic to space the transmission line attachment point at 20 inches.

The wires or rods you choose for a tapered-line section then converge from this 20 inches down to 1/2 inch which presents an impedance of 300 ohms. The longer you make this tapered line, the smoother the impedance transformation. But the 20-in. spacing is wavelengths, so you will have radiation from the tapered line too.
You might want to make the the tapered line just an extension to the rear of the rhombic. Its radiation would then be in-synch with the rhombic`s.

I think I would try a 20-inch transverse insulator to terminate (space) the rhombic at the driven end. Then just continue the two wires in the curtain and allow them to converge more slowly to the 1/2-inch spacing you need for 300 ohms.

At the 300-ohm point you could use twinlead to a 300-ohm / 75-ohm balun. Or you could use a Q-section to lower the impedance to your chosen value.

Best regards, Richard Harrison, KB5WZI

3083. Class A, AB1, AB2, C Tetrode RF Power Amps

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-14 01:10:48 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <96clsa$8ji$1@plutonium.btinternet.com>
Source record: 170358

NOW AVAILABLE :

New Program "TETRODE1.exe"

CLASS A, AB1, AB2, C OPERATION OF TETRODE RF PA's

Obtain a minumum of info from a tube (beam tetrode or pentode) manufacturer's data sheets or curves. Enter in program with DC anode supply volts, DC screen volts, minimum anode volts, maximum control grid volts, required operating angle, intrinsic Q of tank coil, required working Q of tank circuit, frequency.

A useful feature of this program is direct entry by the user of the anode current operating angle. This angle controls the various combinations of linearity and efficiency.

An important data entry item is the control-grid to screen-grid amplification factor, Mu. If the manufacturer's value is not available it can be guesstimated by varying it until other characteristcs become compatible with what info there is available.

The program computes RF power output, anode loss, screen grid loss, tank coil loss, DC-RF power conversion efficiency, peak and DC anode current, DC screen current.

Also tank inductance, tuning capacitance, turns ratio for link winding to 50-ohm load, source impedance looking back into 50-ohm output terminals. Note that a congugate match does not exist at this point.

Grid circuit conditions are computed:- peak RF drive voltage, negative DC grid bias, input impedance, drive power, DC grid current, grid bias resistor, grid current operating angle, grid dissipation.

Covers power outputs from QRP to 100KW.

Push your own precious and delicate linear up to and beyond its safe working limits without any fear of accidentally blowing it up.

Highly educational even if you never use this program in anger.

Download in a few seconds from website below. 52 kilobytes, 1 file only, not zipped up, run immediately.

With an FT-847, you might want to look at a Butternut HF9V, rather than
the 6V. You can use this all the way from 80M to 6M by telling the
radio to use the HF jack for 6 meters. That is what I have on my 847.
Check out www.bencher.com for details.

lbratche wrote:

Probably stating the obvious, but you do realize those vehicles do not
have a steel body, right? You'll have to carry the ground to the
frame, and bond as much metal to it (engine, etc) as you can.

it is type N/M versus PL-259/SO-239. N's and M's mate. PL-259's and
SO-239's mate. N won't mix with SO-239, but you can get adapters.
Adapters add loss, but not much.

> can get if the triplexer only has type "M" connectors? Please set me
> striaght if this is way off base. Thanks!
>
> jmacfarl@visi.com

First, switch the 6 meter output to the HF port on the radio - now you
only have two unprotected ports to worry about. Check your manual for
how to do this - it is a feature of the 847. Then go to
www.cometantenna.com. The have a number of duplexers which will work.
You can get one that has just the right connectors on the radio side
(CF-416C), but you might not like having the N type connector on the
output side. It should be easy to make up a cable to adapt this to your
dummy load (or by an N to UHF adapter). You could also buy the version
which has PL-259s on both inputs and put the adapter on the radio.

This is the duplexer I use to feed my Diamond dual band vertical (for my
847). I use N connectors for the COAX, so I need no adapters in the
signal path. If you are thinking about going to a dual band antenna for
VHF/UHF, you might want to consider this.

Program TETRODE has a little add-on extra. It computes the internal generator (source) impedance, Zs, of an RF power amplifier looking back into the 50-ohm power output terminals. Zs varies with operating angle and is never anywhere near the proverbial conjugate match with ordinary pentodes and tetrodes.

When an amplifier is operating in class AB or A conditions, Zs is constant over the whole modulation cycle to the same extent that the amplifier approaches perfect linearity.

But Walter, W2DU, was quite right when he reported the measured value of Zs to be in the neighborhood of 50 ohms. He had forced Zs to be 50-ohms by adjusting the output tank circuit to develop maximum power into a 50-ohm load. The maximum power transfer theorem never fails whether the load or Zs is the quantity varied.

However, in forcing the issue by using the minimum-dip tune-up procedure, he drove the PA into a saturated non-linear region. Saturation occurs either because the amplitude of the RF plate swings causes the instantaneous plate volts to fall too far below the screen volts, or because available cathode current is insufficient to allow any further increase in output, or perhaps both together.

Because of non-linearity, a very small change in operating conditions causes Zs to shift. Walter mentions the difficulty in measuring Zs as the load is varied a small way from 50-ohms. He used the load variation method to measure Zs.

As the load resistance increases, voltage saturation prevents the load voltage from increasing and the transmitter behaves as a constant voltage generator with an internal impedance less than 50 ohms.

As the load resistance decreases, current saturation prevents the expected increase in load current and the transmitter behaves as a constant current generator with an internal resistance greater than 50 ohms. (Pentodes and tetrodes. We are in the same operating region as covered by the computer program).

This is a serious matter because the only reason we would like to know Zs is to predict what happens when only the load resistance changes (SWR no longer 1:1). But as soon as the load resistance changes the internal resistance changes a good deal faster.

So after performing a minimum dip, the knowledge that Zs is in the 50-ohm ball-park is of no use. In fact, changing anything, especially the changes which occur during the modulation cycle, shifts Zs.

Walter was right !

Hello:

I am looking for an antenna that covers 30 to 88 MHz for l Watt transmit
(PRC-126).
The AS-1729 has as about 8 dB loss in some places in the band.
Are there more efficient mobile antennas available.
The OF-254 does this for a fixed location.

73,

Brooke Clarke, N6GCE

I believe that impedance IS R +/- jX. I think your early model gives only R.
In this case, impedance cannot be calculated from the data from earlier
version.

Mark,
I get plenty of 6 meter from Texans on SSB so go ahead and get
horizontal - you're in a good positon to work much of the continental
US when the band is open.

As to the first poster's question: for starters make a dipole from some #14 wire it's easy and they work - besides at 6M it's easy to get them 1/2 wave above ground. As Mark mentioned, the ARRL antenna book has what you need to build a 6M yagi and I suspect that the RSGB publications do also. The other option is to go the Cushcraft website and download their manual for their 3 element 6M beam as it has the dimensions and would be another good starting point.
http://www.cushcraft.com/

Good luck,
Howard

Is the band still opening up as far as F layer very often? I haven't kept up with it as far as the solar cycle goes. It's seemed to be a pretty flat cycle to me overall, but I've listened on 10m much more than 6m. It doesn't seem near as good as last cycle in 89 ??? or so. So far in listening on 6m I've heard no skip signals, but I guess it could be just because no one is talking. I bet it will perk up if I listen during a contest.. Also I guess a better antenna could help. I get a bit of crud on that band because I'm about 8 miles from a 2000 ft CH 2 tower/ant. It whacks me pretty good , but I'm trying to work around it.

There are established techniques for using 200-ohm line with very low loss for 432MHz moonbounce.

In particular, the lower-impedance line lends itself nicely to semi-rigid construction using spaced rods with minimal PTFE support. You can then make a two-slug tuner using two sliding blocks of PTFE. These look like giant two-hole balun beads, which the line passes through. By sliding them up and down the line you can position the two sections of lower impedance to cancel a wide range of mismatches.

Having a means to adjust the matching, you can use a very 'casual' tapered line transition from the rhombic feed impedance, and tune out almost any kind of mismatch (if it won't tune, you only need to alter the line lengths to bring it into range).

Sorry, I'm not quite clear whether the original request was for 50- or 75-ohm matching; but it doesn't matter much. The half-wave loop for a 4:1 balun should be made from UT-141 semi-rigid or something with even lower loss (50-ohm cable is OK for a 300-75 ohm balun). Alternatively, at 23cm a slit-sleeve 4:1 balun may have even lower loss.

Unfortunately the relevant articles are not on-line, but you can go to www.dubus.org and follow the links to the contents pages of the DUBUS-TECHNIK books to find the article by DJ9BV. The Australian rep for DUBUS publications is Doug McArthur, VK3UM - a telephone call to him may be very useful.

Richard,
Thanks very much for your info,
let me just double check with you,the tapering should be approx 1
wavelength ,,,the feed should taper from 2 inches(you have 20 maybe typo)
to 1/2 inch to reduce to 300ohms,then a 1/4 wave of 75ohm to drop it to 50
ohm area,,
I got the frame and wire built hope to have a shot at the feed
soon,
Thanks again Richard,
Paul......vk3ddu

From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <96dtfaqii1@uranium.btinternet.com>
Source record: 170276

From Z and SWR, R and X can be calculated. But the sign of X is ambiguous.

To determine the sign of X it is necessary to inspect the item being measured. For example, if the antenna wire is open circuit at the other end and its length is less than 1/4-wavelength, then input X must be negative.

The sign of X can also be investigated by connecting a capacitor or coil in series with the unknown Z and observing what happens to Z.

Arithmetically -

R = (2500 + Z^2) / 50 / (SWR + 1 / SWR)

X = Sqrt(Z^2 - R^2)

Angle = ArcCos(R / Z)

However, measurement uncertainties can be greatly magnified when passing through the arithmetic. X is related to the small difference between two large quantities.

In the "47 KW CB" thread days I thought a matched load meant 50% power loss in the source. Walter insisted it wasn`t so. Walter was right!

The source is not a perfect switch, but if it were, its on-off cycle could be set for 50% with np loss in the switch. Power in the load would average 50% of the continuously-on power.

The effect is the same as 50% loss in the source but without source dissipation.

Walter called switched-off time dissipationless resistance. That seems a fair characterization.

The Bird Model 43 will last almost indefinitely. With the appropriate plug-ins it covers 0.45-2300 MHz and 0.1-10,000 watts. It is reasonably accurate. At any time after purchase you are likely to recover more of your investment were you to liquidate.

It reads watts in each direction but is supplied with a chart for equivalent SWR.

A 1/2-wave dipole up 1/2-wave above earth?

My 1998 ARRL Handbook has optimized 6-m yagi designs. 3-element and
5-element designs are offered. Gains are 8dBi and 10dBi. Front to back
ratios are better than 22 dB for either. SWR is better than 1.6:1 from
50 to 51 MHz. Boom lengths are 6 and 12 feet.

My RSGB VHF-UHF Manual doesn`t seem to include 6m yagi antennas.

> don't remember his name but I remember his friendly attitude, and his laugh.

W6CCW was Manny Nevalhas, a real ham's ham - always ready for an
eyeball QSO. I'd go to Quement's at least once a month, hit the
Coke machine, and check out the latest trade-ins on the used equip-
ment shelf. Manny would usually offer to liven up my Coke a bit
with a little shot of Four Roses...never took him up on it. Maybe
the Four Roses is why he was always so friendly and in a good mood.
He's probably a Silent Key by now.

You couldn't miss Frank Quement in the store. He was a big guy,
like HP's David Packard, and wore a big button on his shirt that
said "Ask Me".

Quement's started to go downhill after Frank became a Silent Key.
I believe his family tried to keep the place going, but it was
never the same again.

3109. Scanner Antenna Question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-14 17:51:44 UTC
From: jimdpeters@aol.com
Message-ID: <20010214125144.28005.00001044@ng-ci1.aol.com>
Source record: 170283

I'm thinking of buying a new scanner antenna. The two choices I have narrowed it down to are the "SCANTENNA" and the "DIAMOND D130J DISCONE" antenna. Has anyone had experience with both that can let me know which one is the better antenna?

From: Henry Kolesnik <wd5jfr@oklahoma.net>
Message-ID: <t8ljcidbfb24bb@corp.supernews.com>
Source record: 170284

i have an HP117A rx for WWWVB..
the matching antenna is a 43 inch loop..
the HP 10509A, with 2 13CW4 nuvistors..
it's to big to ship by UPS so i'm looking for reasonable options..
it will fit into 2 bike boxes and can be checked as air baggage for an extra $75.00..

listed below are my questions:
1. how many turns of wire are there in the aluminum loop?
the schematic shows 1500 & 270 pfd caps across the windings feeding each of the grids..
according to the notes these caps are selected or may be omitted..
it's center tapped which is grounded..

2. how does this loop work with the turns inside aluminum tubing? why doesn't the tubing act as a shield?

3. the nuvistors, 2 13cw4 may be hard to find for replacement and i wonder if anyone has developed a mod for FETs..??

can this thing be knocked down without destroying it so it can be ship by regular UPS??

i'm in Tulsa and it's in Maryland..
tnx

Hi Richard,

This is simply the difference in thinking of the Thevenin Generator requiring an R to match when Thevenin actually (classically) requires a Z (and was the lesson our friend John Fakan tried to communicate to us some two years ago with his homopolar generator). It also relates to what I tried to characterize as the closed loop source Z instead of the open loop discussions that were going on at the time.

There's room for everyone to find their answer in the same data, but that doesn't necessarily translate into a proof of their assertions made then or now; except as observed, Thevenin is satisfied with the measurement that Walt made. That this seems to surprise....

Punchinello's comedy of errors was driven by the trolly myopic approach of looking at each degree of conduction, which devolves the discussion to a steady state solution that in turn expects an R to perform the conjugation. This linear thinking fails at the world view where Z handles the occasion without fuss, old wives' needs, or extra theories on the meaning of the universe, life and everything.

I have built several dipole type antennas for 2m use.
Some used old aluminum TV antenna elements cut down to size and found that they seem to match 50 ohms best when in a "Y" configuration with the coax being the bottom part of the "Y". I could never could get a "T" configuration to read a flat 1:1 SWR. I was using a MFJ antenna analyzer to read SWR.

Jim, is the Scantenna a beam type antenna?
If it is then it will preform better than a discone in the direction it is pointed.
The discone type antenna has no gain and is good for omin-drictional use.
If you choose the D-130 discone try removing the top loading coil and whip assembly .... or replace it with a 60" whip with no loading coil and see if it improves the reception of the lower and mid frequencys.

Hi Henry:

1. don't know
2. the loop is not continuos, like all shielded loops there is an insulating gap.
3. the nuvisotrs show up, keep an eye out. There are also nuvistors in the 117 60 KHz amplifier box.
If anyone has a FET replacement scheme for any of these I would like to also know.
4. No way that I know of to disassemble the loop.

John,

It was not long after the death of Mr. Quement that the HAM dept was
closed down. Within a shockingly short interval of time after that the
heir's closed the store to retail trafic and concentrated on being just an
electronics distributor. They blamed it on Fry's, Good Guy's and other
electronic retailers.

I long for the return of the Bascom Bandits! Now all we have in the Santa Clara Valley is Ham Radio Outlaws...

Source record: 170296

A simple dipole will never read 1:1 if it is far enough away from other
things that can influence the impedance. The dipole is normally around
70 ohms and the coax (in your case) is 50 ohms. This is automatically a
1.5 to 1 best case.

William Lee wrote:

Hi,

I am sure this question has been asked a million times but I never payed attention since I never had a dual band radio, 2M/440.

Soooooo I was wondering if anyone has any good or bad comments on various antennas. I am used to using 5/8 commercial antennas for VHF, antenna specialists, Larsen.

Regards,

Matt

That was the clincher. Walt is too honest to fudge data and he is to competent to make any serious errors. Anyone can make a big mistake, but Walt clearly did not. I still need to reconcile some issues, so I have more to learn about matching r-f power amplifiers.

Best regards, Richard Harrison, KB5WZI

Never say never.

A dipole placed in the right environment (distance from ground and
other objects) it is very possible to have a dipole's feed point
impedance to be 50 Ohms and provide a SWR of 1:1.

Source record: 170301

Lyle Kohler has a couple loop preamps written up and posted on his web site. I built one of them, which should work well with the antenna you describe. It has a high impedance balanced input. The version I built is remote-tuneable, which might not be necessary in this case. You'd want to make sure the output transformer would handle 60kHz OK, maybe a bit higher inductance than what Lyle's schematic shows, though the version I built seems to work well down below 100kHz.

Re the shield: one very effective way to view it is that the shield is the antenna, and the gap in the shield is the feedpoint of the antenna. The voltage given by Faraday's law relating the changing magnetic field within the loop and the voltage around the loop is delivered by the good conductor of the loop to the gap. There is a nice description of this in King, Mimno and Wing, "Transmission Lines, Antennas and Waveguides." This construction has the advantage that you can make the loop extremely symmetrical, and thus avoid sensitivity to voltage fields; if you can make the loop symmetrical enough without the "shield", it should perform similarly, and I believe that making it balanced with a grounded center tap and feeding a carefully balanced preamp will go a long way to making that happen. So it may be possible to get good performance for the 60kHz receiver by constructing a new loop, too. But be aware that there gets to be a lot of wire in a LF loop: you can estimate the number of turns if you know the external capacitance by using Reg Edward's loop (loop3, I think it is) program. In any event, you can design your own with that program. But for instance, a 40 turn loop 5 feet on a side represents 800 feet of wire.

Cheers,
Tom

3128. Bobtails/Half Squares- A Few New Pages

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-15 08:15:09 UTC
From: k3ky@erols.com
Message-ID: <3a8b8b38.715308@news.erols.com>
Source record: 170302

For those interested in these antenna types, I have added some new
material to my Bobtails and Half Squares pages.
As always, the entry point for this series is "The Low Bands":
http://www.angelfire.com/md/k3ky/page20.html
There is a new page with some comments about high band
versions of these antennas, low bands 'benchmarks', and an
interesting 17 meter design by NJ0F:
http://www.angelfire.com/md/k3ky/page44.html
This is a work in progress and is offered only to stimulate
further research and experimentation by interested users.

There are also some new photos of various LC matching
networks and also a collection of photos taken by W7AV
of his new 40 meter half square in WA. He reports good
success DXing with the antenna. These are all available
as links from:
http://www.angelfire.com/md/k3ky/page41.html

3130. How to measure self-resonant frequency of solenoid

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-15 10:19:56 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <96gag3$62k$1@uranium.btinternet.com>
Source record: 170303

(1) Place a single turn, close-coupled, link winding around the centre of the solenoid.

(2) Connect it to an Autek or MFJ antenna analyser via a loosely twisted-pair line about 10" long.

(3) Switch the antenna analyser to the Z range.

(4) Suspend the solenoid in mid-air.

(5) Z will be in the range 0 to a few ohms. Vary frequency slowly searching for a very sharp, resonant increase in Z.

Maximum Z will very likely be in the range 50 to 500 ohms at the self-resonant frequency. Q will be extremely high, too high to be determined from the 3dB points on the resonance curve.

The method works for solenoids 2 or 3 inches long, and for helically-loaded dipoles, 1" diameter, 6 feet long.

Its an old wives' tale that Q is poor when most of the capacitance is of the parasitic variety. Unless frequency is varied very slowly the resonant point will be missed.

Program SOLNOID2 predicts the self-resonant frequency before you've wound it. Program MIDLOAD deals with continuously-loaded dipoles which are just very long solenoids damped by radiation resistance.

3131. Re: Dipole for 144MHz-indoors??

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-15 11:03:41 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <96gcvt$k3a$1@neptunium.btinternet.com>
Source record: 170304

When a dipole's impedance is adjusted to 50 ohms by positioning it relative
to ground and nearby objects, it has been done only by increasing losses and
degrading radiating efficiency.

But no loss in efficiency is caused by bending it in the middle and calling
it an inverted-V. The radiation resistance then decreases nearer to 50 ohms.
But all this does is reduce the already small feedline loss on a 50-ohm coax
due to an SWR of 1.5 : 1.

If feedline loss causes a loss of sleep then the best tactic is to use a
75-ohm coax feeder which is a perfect match to a high 1/2-wave dipole.

But even this is not the ideal cure for insomnia - SWR and feedline loss
at HF return to their worrying values at the band edges.

However, at VHF, although a dipole feedpoint impedance will change less over
the band, invariably the directing and reflecting elements will shift
feedpoint impedance well away from 50 or 75 ohms anyway.

3132. Re: Good beach antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-15 14:34:17 UTC
From: Bruce Muscolino <w6toy@erols.com>
Message-ID: <3A8BE8E9.C8292423@erols.com>
Source record: 170305

David,

Laying a dipole on the beach would not be a very good idea. To begin with the antenna would be pretty much grounded! Secondly to operate efficiently a dipole should be at least 1/2 wavelength up in the air! For a beach operation like you want I would suggest a vertical antenna. There are a number of fiberglass or composite "crappie" fishing poles that collapse to 4 to 6 feet that you could carry on the airplane. Examples are the SD20, which is now readily available from WorldRadio. You run a wire up them and use it as a vertical. Don't forget that a vertical depends on a good ground at its base!

Source record: 170308

Reg gave easy directions for measuring self-resonance in a coil.

Reg`s statement: "It`s an old wives` tale that Q is poor when most of the capacitance is of the parasitic variety." was inserted to draw a response, I suspect. Q usually depends upon high capacitance in a resonant circuit.

For any resonant circuit, its frequency is a constant when the product of L and C is a constant. The same resonant frequency can be obtained with high C and low L, or high L and low C.

High L and low C is the case of the self-resonant coil. A high-L resonant circuit maximizes the lossy element in a resonant circuit.

Q is the inductive reactance of a coil divided by its resistance. In most resonant circuits Q is the same as the coil Q because a properly made capacitor has very low losses.

A self-resonant coil is a coil without added capacitance in which most of the capacitance is of the "parasitic" variety. As such, the lossy coil is maximized, the low-loss capacitance is minimized, and the Q of the resonant circuit is relatively low.

Best regards, Richard Harrison, KB5WZI

It has been my experience that if you don't get an answer the first
time, ask the question again. In all probability, the right people
to answer your question just didn't see it the first time.

> You asked for help on a 6 meter tuner. MFJ makes one. Go to their site

I have downloaded a couple of the MFJ manuals and the one thing that
is not included in them is the schematic. For some odd reason they
cut them out. Otherwise the manual is complete.

But if the original question was about antenna tuners, go page through
a couple issues of the ARRL handbook. There are always lots of info
on antenna tuners. Another option is to go to "http://www.arrl.org"
and do a search on "antenna tuner". You will find lots of info.

3135. Diamond D-130J discone performance

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-15 17:00:48 UTC
From: Michael <hkc2001@pacbell.net>
Message-ID: <nUTi6.6$te3.9001@news.pacbell.net>
Source record: 170309

I just got the Diamond D-130J discone antenna. When I connect it to my MFJ-259B, I was surprised to find that in 20-70M range, it has a very high SWR(mostly around or above10). Even on 2m, it's above 2. The lowest SWR is around 114. Does that kind explain why I am not getting good reception out of it? It's rated to transmitt to on 6m, but how come it has such a high SWR(above 6) around 50M? Any suggestions? Is there any improvement I might try? thx.

3136. Re: Diamond D-130J discone performance

I have a Diamond, I don't know if it is the same model. The typical discone, has a verticle, base loaded element which has to be tuned for 6 meter operation. The cone itself should be useable over at least a 3 to 1 frequency range. So if you found a dip at 114 I would guess that is its bottom frequency, and you should be able to use it up to around 450 or higher. I use mine for 2 meter transmiting, and listening on 430 to 460. Gives me more coverage than I need. Copies the ISS on 143.625 at the horizon better than my Eggbeater, but not as well at high angles.

When I got my first dual-bander some years ago - my first dual band antenna was a Larsen NMO 2/70.. My second one was also, as one day shortly after I got it, I arrived at work with all the antenna missing, except for about half the coil. I contacted Larsen, who replaced the antenna complete, after they determined a manufacturing defect in the coil....used that for a little while till I couldn't keep the whip from turning green, about 2 years... then I bought a Diamond NR770HNMO - this antenna will out talk the Larsen by double, it doesn't turn green, and I still have it 11 years after I bought it (and still works as good as new)... a little pricey, but ya get what ya pay for....

This antenna is not a discone below 110 MHz. On VHF LO it is a ground plane. The vertical whip with a loading coil provide resonance over a VERY narrow segment of the 30-50 MHz range. The difference in reception (and TX) between a 2:1 VSWR and 1:1 VSWR is pretty much imperceptable. How long and what type of transmission line are you using?

3141. 2.4Ghz directional antenna for LAN (home RF)

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-15 18:13:16 UTC
From: mindy <mindy1701@hotmail.com>
Message-ID: <3A8C1C31.54F974A1@hotmail.com>
Source record: 170315

Hi All

Iï¿½m trying to extend the range of my wireless (2.4Ghz Spread Spectrum)
LAN system in my house.

I need to extend it to around 1000ft ï¿½ Standard is 150-200 ft with the
Omni
directional antennas. It only needs to be point-to-point, so a
directional antenna
will work fine. The path is all line of sight with a single tree about
half way.

The transceivers have standard dipole antenna on them. They appear to be
either
0db or ï¿½3db dipoles.

My though was to build either a Helical or a Yagi antenna with an
appropriate
gain to overcome my losses. I figure the gain should be +9db for the
extended
range plus all the cable and connector losses.

I am an electrical engineer, but I have no experience in antenna or RF
design.
I have a HP network analyzer at my disposal, so can make measurement on
the system.

Now here is my question:

1) I would prefer not to tear into the transceiver and attach the coax
to the circuit
board.

Is it possible to couple the signal to the existing dipole
efficiently enough to make
this work ?

What would be the loss if I ran the output of, say an 18db
helical antenna,
through a coax to a ï¿½ wave dipole and place it next to the
transceiverï¿½s
antenna. ?

Does this idea have any chance of working ?

If so is there an optimal position or configuration that I can
employ?

Is there any impedance issues that I need to deal with?

2) If I have to tear into the transceiver and connect the antenna directly to the
circuit board, I assume that the impedances are not going to be matched.

What will I have to do to match it close enough to work ?

Any other Ideas would be greatly appreciated.

Thanks
Mindy

Source record: 170317

I can think of a couple of considerations, for an antenna to be used on the beach. One is corrosion. If it's at the beach for very long at all, corrosion will be a rea problem. Something like the St. Louis Vertical (http://www.fix.net/~jparker/slvt.html, http://www.superantennas.com) is useful for portable operation but in its common implementation requires a clip connection to a loading coil. This arrangement would have to be modified to make an antenna that would put up with salt spray for very long. Another consideration is the ground system. Someone else pointed out that a vertical produces tremendous low angle radiation when it's beside salt water, so it's really attractive to take advantage of this. A quarter wave vertical does require a good ground system. I'd guess that just a couple of radials would be adequate on the beach, but these can be a nuisance and a hazard if there are other people around or other activities going on. (You could bury them a few inches, though.) With a half wavelength vertical, you can get by with a very simple ground system -- a four foot ground rod would probably be adequate. But it'll corrode quickly too, unless made from something pretty resistant to salt water. It'll be a bit of a challenge, but it'll be fun and I'm sure worth the effort.

It's a piece of cake actually. Just shift the center point of the dipole one way or the other to get a perfect match to the coax. Wouldn't have to shift far on a VHF dipole. Kinda like adjusting a gamma match in a way. MK

Can you position it in the focus of a 5 foot parabolic reflector? That
won't require any low loss coax, tearing into anything, or building a device
which will require 0.05" precision in construction.

Call Hy-gain. They are still in business. I don't have their number in front of me but just do a search on the internet for Hy-gain and the web site will pop up. I just talked to them a couple weeks ago about a new base for my 14avq that shorted out. Also they have a good tech support group there.

Peter, K1PO wrote:
"The Conjugate Matching" Theorem, etc. is a subject or theorem only of interest to the designer of loads, NOT to the designers of sources.

Whether maximum power transfer happens or not, the impedance presented to the final amplifier is important to the deesigner. The load impedance determines power output and affects dissipation in the final amplifier.

Maximum power delivered is the peak voltage times the peak current divided by 2. The value of the load impedance is the peak voltage divided by the peak current.

Modern transmitters are usually designed for a 50-ohm load impedance. This is important to harmonic suppression and overload protection circuitry. The designer is definitely interested in the load impedance presented to the transmitter.

The transmitter is coupled to the transmission line through a matching networlk (tuner). Why use a tuner? To load the transmitter properly.

I did add a qualifing statement to the posting. The antenna in question
was a two meter antenna and a simple dipole. It was not stated to be
fed off center or close to any objects. I am well awear that a dipole
can have almost any value depending on where it is located. I have a
dipole for 80 meters that is only up about 20 feet and it does have
almost a 1:1 swr at one frequency around 3.8 mhz because it is close to
the ground.

A discone is a broadband solution that may not fit well with your mobile. My 15th Edition of the "Radio Handbook" has a version good for 11 through 2 meters. The disk is 6 feet in diameter. The skirt has a diameter of 9.5 feet, and a slant height of 9.5 feet.

Another way would be to adapt a screwdriver antenna or a broadcast power antenna. Either would be set for the frequency being used at the moment.

Hi Peter,

This is not the experience that I have had in linear design, in fact it is the concern (the source matching the load, not the load matching the source) of many linear systems. This is such a commonplace issue of design, that almost every spec sheet for linear components covers it in their specification (which seems to be wholly ignored by those who claim designers have no interest). And, this is not to limit such considerations to linear design. I have many logic designs who impose a restriction to loads in what is called "fan-out." This too, is specified by every logic vendor. If you believe that I have no interest in the internal resistance of the battery that drives my design, or the re-charge circuit that in turn drives it - then you inhabit a world free from care.

Ignoring those considerations is too simplistic and serves no useful purpose otherwise.

I am sure there are a world of designers who toe the line of your comment; and I am equally sure they produce nothing of special regard either. That is, there are many instances where such consideration is wholly outside of meeting necessary requirements. But even here, this is more the matter of the eventual design's flexibility (or ability to be forgiving). In that regard, ignoring these considerations may be absolved through over-design (or even sloppy, inefficient design); but

this does not make it a good engineering practice (unless you are a production engineer, as distinct from an R&D engineer).

Back in the late '40's in NYC there was a fellow by the name of Mad Man Muntz who built TV receivers. His standard design practice was to visit each engineer who was working on a piece of the design. The Mad Man always carried a pair of dikes and would whip them out and snip out parts of the bread board until the circuit failed. His advice was always: "replace that last part and ship it!" This is the art of production engineering and it has its basis in the formalisms and academic concern, but they only evidence themselves in the circuit's failure. The Mad Man probably didn't give a damn about these formalisms (he was a car dealer anyway) insofar as how to make a circuit work, but he certainly trusted them when his last snip disabled product.

Mad Man Muntz shipped TV's without extravagant circuits like horizontal stabilizing/synchronizing because his TV's were aimed at city environments where the signals would be guaranteed to be strong and issues of synchronization were already enforced by the quality of the existing signal. (I, on the other hand, often found myself trying to "repair" such TV's for folks in the boondocks. Yes a fool's mission.)

If I thump the tub to loudly proclaim the necessity of matching source to load, it comes from years of experience that showed nothing less would satisfy. That this concern is treated with care and deep coverage by the vendors and users of linear components, this too speaks of the reality of such consideration that has been manifest for decades now.

That there are some amateurs here who routinely neglect this coverage of the past 40 years suggests they lost the capacity to care, or that it is not perceived to be a problem. This last (the perception) is not an argument for-or-against, it is simply a prejudice. The first (the lack of interest in the coverage) has no argument ('t'ain't so does not qualify as argument).

I see wide variations depending on the surroundings and height. But you were correct in the orignal part, a dipole in "virtual" free space will almost always show a 1:4-1:5 to 1 SWR. Of course, the difference in signal is unnoticable, but this will limit the available bandwidth that will be usable with a solid state rig if you are limited to 2:1 SWR. I like the center point shifting, because no matter the surroundings or coupling, etc problems you could have, you can still get a good match. Which just means you have more usable bandwidth considering a picky rig. Of course, you will be slightly unbalancing the antenna, but I've never noticed any adverse results from doing this. MK

"Any other ideas would be greatly appreciated."

At 2.4 GHz your wavelength is about 4.9 inches. You can make a
right-angle corner-reflector about 1 wavelength on a side (5 inches).
Place your 1/2-wave dipole about 2.5 inches from the apex inside and
parallel to the corner.

The reflector adds about 10 db to the dipole.

Antenex makes a couple of great dual band antennas for the ham bands. One is a standard closed collinear 2db gain on VHF / 5db gain on UHF model, and the other is a short version which is unity gain on VHF and probably 3 db on UHF. I've been using the longer one for the last 2 years and haven't had any problems with it. I have a friend who uses the short one and has no complaints either. You can even get these in a black finish, which in my opinion looks much better on a vehicle.

Once again we have an illustration of trying to reduce a great deal of widely varying information about pattern, efficiency, and communications effectiveness into the binary pigeonholes "good" and "bad". The result is predictable, and there will never be a consensus. Why can't people realize that what's best for one particular situation or under one set of circumstances isn't good for another? That it takes more information than "good" or "bad" to determine whether a particular antenna is suitable for a particular application?

Sure, I could use a T2FD for an 80 meter QRP station. I could even talk to a few people. But I'd put out a much stronger signal and be able to talk to a lot more people with a half wavelength dipole, or even a center loaded shortened one. If I had to carry an antenna on my back and set it up within a few minutes nearly anywhere, had adequate power, no tuner or a limited range one, and had to communicate with other relatively high powered stations on just about any frequency in the HF range -- or if I had a frequency-hopping radio that covered several MHz, the T2FD would be a much better choice than an 80 meter dipole, or just about any other antenna. So tell me, is the T2FD "good" or "bad"? How about the 80 meter dipole?

I remember many years ago going on a tour of a multi-state central emergency control center at the Denver Federal Center west of Denver. It also was underground. They'd stockpiled food and medical supplies, with an emphasis on supplies to treat radiation casualties. There were seats for the directors of the several states to sit and direct distaster operations. When I asked how they were supposed to get there from their respective states, the answer was that they were to come via commercial transportation (really!). For communications, they had a multi-kW transmitter that could autotune to any frequency in a few seconds. It was connected to a log periodic antenna on a tower outside. This was their only antenna, and it could have been easily dropped by a microburst, good windstorm, saboteur, or of course any kind of strong explosive blast. Floods and downpours are common there. If the place didn't leak, there could be periods when no one (including the alleged incoming state directors) could go in or out without letting in a whole lot of water.

Presumably, the lower level disaster agencies were to be coordinated or to take their orders from this facility.

It was a very worthwhile tour. It taught me that I, not the government, am most likely going to be my best friend when a disaster strikes.

I listened for hours to contnuous Hurricane Carla coverage by Dan Rather from KTRH in Houston. I was in Tierra del Fuego Argentina some 6000 miles from Houston. My radio was a hand-held Hitachi with a built-in loopstick. Oh yes, I set it down and still heard very well. One advantage to being not far from the South Pole is a very quiet listening location. Thunder and lightning are completely unknown. KTRH radiates 50 KW with a north-south directional array. That helps on this path.

The best antenna I`ve used is a Beverage that I used in Europe to nightly listen to stations in the USA. It has an excellent signal to noise ratio due to its high directivity.

Richard:

I see that you feel strongly about the "maximum power theorem" and have now apparently elevated your "belief" in this "mantra" to the level of a religion. Was/is Fred Muntz a messiah? What?

Be that as it may... beliefs aside, let's consider the use of laws of physics and rules of mathematics rather than recalling historical incidents of sloppy engineering.

Richard, the maximum power transfer theorem provides nothing more nor less than the prescription for the value of a load impedance z to be used to extract the maximum power from an existing fixed source which has an impedance Z already designed by someone else.

In other words only the optimum value of the load is being sought by the maximum power transfer theorem, and not the optimum value of the source impedance!

The load is the independent variable, the thing being "designed", while the power is the dependent variable, depending upon the load being designed. The source impedance is merely a constant in that calculation! The source impedance is not the value being sought! Rather it is the value of the load impedance being sought. Is that not the design of a load? No?

What?

In other words, for the purposes of the so called "maximum power transfer theorem" the source impedance is considered a fixed (complex) constant, while the load impedance is considered to be the variable or "unknown" which is sought by the designer and which is to be varied until it reaches the value which extracts the maximum power from the given source.

In simple mathematical terms, the Power P is the dependent variable. This power P is calculated by the usual formulae and it is the power that the load designer wishes to be extracted from a fixed source of impedance Z=R+jX and delivered to the variable load z=x+jr being "designed" by the "designer.

Here P is a simple function of z. In functional notation, it is P(z).

By simple application of the complex differential calculus, i.e. by differentiating P(z) with respect to z and setting the differential to zero and solving the resulting equations for the value of z which makes dP/dz = 0 one finds the unique value z = R - jX.

P(z) can be proved to have a unique maximum. This occurs only when the load impedance z = Z = R-jX. i.e. when the load z is equal to the complex conjugate of Z.

This "so-called" theorem, the application of that name which any "mathematician" would laugh at since it is such a trivial mathematical result, is easily proved by application of simple differential calculus.

In other words, as your math teacher would have said, finding the value of z that maximizes P is left as an exercise for the student!

What the hexx finding the maximum of P(z) over z has to do with the design of a source impedance Z is surely nothing.

Let's find another theorem for what you propose! Call it the optimum source impedance theorem, or whatever...

As the little guy on TV used to say, you can call it Ray, or you can call it Ray Jay, or you can call it.... it's still a load designer's theorem!

In other words to meet your needs, we need to ask another question, or pose another theorem.

Surely what you are interested in as a designer of sources rather than of loads is...

What is the optimum value of the parameters of my source (a.k.a.) amplifier impedance, or whatever, required to deliver the maximum power to my given fixed load?

In other words, let Z be the independent variable and let z be fixed, then calculate the value of Z that maximizes P(Z).

That, my friend is what is of interest to the designer of sources.

Richard, do you have any idea what that value of Z would be? Is it unique, is it a useful result?

What?

I have a limited space to install an antenna but I could get a wire up about 25'. Which would work better for all band 80-10 meters. A 135' doublet fed with ladder line or a full wave 80 meter loop fed with ladder line?
Thanks
Steve

If you need a helpimg hand, you look to the end of your arm, right?

Planners make mistakes. Some would be comical if they weren`t serious. Our sheriff has had his shakedowns and his stuff works.

There was a National Geographic PBS special TV program last night on "The Storm of the Century". It was in the last decade and it started in the Gulf of Mexico and swept all the way through New England with tornados and blizzards. It was the most damaging storm ever recorded but the 1900 Galveston storm is the worst killer. The Storm of the Century happened in Mid-March.

Weather forecasting and relief efforts were featured. Police, firemen, National Guard, Coast Guard, and broadcasters who recruited civilian volunteers to handle emergency traffic and killed their regular programs were shown. Rescue seemed to work fairly well. Helicopters plucked victims from perilous situations though some victims froze or were drowned.

Notable by their absence in the TV coverage were amateur radio operators. Some must have handled useful traffic and not just talked about the storm. Why didn`t National Geographic show them?

Best regards, Richard Harrison, KB5WZI

3163. Texas Antenna Legislation, H.B. 1148

X-Mailer: <IMail v6.00>

ALERT - FROM jhaynie@arrl.org via arrl-mailer@jupiter.interbridge.net

TO: ALL TEXAS ARRL MEMBERS
FROM: JIM HAYNIE, W5JBP, PRESIDENT, ARRL

RE: TEXAS BILL H.B. 1148

There has been much concern recently about the potential impact of H.B. 1148, introduced in the Texas State Legislature by Representative Robert "Robbie" Cook (28th District). Hundreds of ARRL members have contacted me urging ARRL involvement in protecting the interests of Amateur Radio operators in the state.

Here's the issue: Many Amateur Radio operators fear that this bill, if enacted, could inadvertently impose some very difficult bureaucratic requirements on any attempt to erect even the smallest whip antenna.

I have spoken with Representative Cook's office and that was not his intention. The bill was supposed to deal only with commercial structures. When informed of the concerns of ham operators, Representative Cook's office invited an amendment to ensure that ham operators would not be affected.

I have sent the following amendment to Representative Cook's office and they are willing to put it into the bill:

Sec. 240.082.5 EXCLUSIONS: Nothing herein shall be construed to regulate, nor shall it regulate, antennas, antenna support structures, devices or facilities, installed, maintained and used exclusively for Amateur Radio communications by Amateur Radio operators licensed by the Federal Communications Commission.

Rather than continuing to alert me about this bill, Amateur Radio operators in Texas may wish to contact Representative Cook at the State Capitol to indicate their support of this amendment.

3164. Texas Antenna Legislation, H.B. 1492

FYI, A couple of days ago, I received the following email from ARRL concerning the Texas legislation, H.B. 1492.

Bob
k5qwg

Date: Wed, 14 Feb 2001 16:35:13 -0600 (CST)
from: jhaynie@ARRL.ORG
to: bamiller@texas.net
subject: ALERT TEXAS H.B. 1492

Yesterday I sent you a message about Texas House Bill 1148 but failed to include the contact information for Representative Cook. They are as follows:

TEL (512) 463-0682
FAX (512) 463-9955
email: robert.cook@house.state.tx.us

Now we have another bill sponsored by Representative Rick Hardcastle, bill number 1492 that would require amateurs with towers higher than 50 feet to paint and light with appropriate markings for aviation safety. I urge you to contact Representative Hardcastle's office and voice your objections to his bill and exempt amateurs.

> By Hardcastle H.B. No. 1492
> 77R6141 JAT-D
> A BILL TO BE ENTITLED
> 1-1 AN ACT
> 1-2 relating to painting, marking, and lighting requirements for
> 1-3 certain antenna structures.
> 1-4 BE IT ENACTED BY THE LEGISLATURE OF THE STATE OF TEXAS:
> 1-5 SECTION 1. This Act may be called the LeClair-Jennings Act.
> 1-6 SECTION 2. Subchapter B, Chapter 21, Transportation Code, is
> 1-7 amended by adding Section 21.069 to read as follows:
> 1-8 Sec. 21.069. PAINTING, MARKING, AND LIGHTING OF ANTENNA
> 1-9 STRUCTURES. (a) The department shall adopt rules to establish
> 1-10 painting, marking, lighting, and other visibility requirements for
> 1-11 antenna structures that are at least 50 feet but not more than 200
> 1-12 feet in height above ground level.
> 1-13 (b) The rules adopted under this section shall be similar to
> 1-14 the rules for antenna structures more than 200 feet in height above
> 1-15 ground level under 47 C.F.R. Part 17, Subpart C, and its subsequent
> 1-16 amendments.
> 1-17 (c) In this section, "antenna structure" includes the
> 1-18 radiating or receiving system, its supporting structures, and any
> 1-19 appurtenances mounted on the radiating or receiving system or its

> 1-20 supporting structures.
> 1-21 SECTION 3. This Act takes effect September 1, 2001.

His address is:
Richard Hardcastle
Capitol Phone (512) 463-0526
District Phone (940)553-3829
e-mail: rick.hardcastle@house.state.tx.us

Please note that I am sensitive to mass e-mails as I get them also, but these two issues are very important to amateurs here in Texas, and I need for you to be aware of events that affect you and amateur radio.

Sincerely,

Jim Haynie, W5JBP
President, ARRL

Dallas, Texas

3166. Crude dipole antenna in roof crawl space

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-16 03:26:08 UTC
From: Robert Casey <wa2ise@ix.netcom.com>
Message-ID: <3A8C9DD0.812F1660@ix.netcom.com>
Source record: 170240

I've had apartments in 2 to 3 floor wood frame
construction buildings with peaked roofs. I've
been able to open the access hatch and stick my
head into the space. But it's not really possible
to walk up there. What I have done is take some
wire and tie weights to the ends, and toss as far
as I can the weights with wire to make a horizontal
antenna. Do it twice in opposite directions and you
can produce a crude dipole. I figure I made a dipole
with about 12 to 14 foot legs. Terrible SWR, but my
TS440S with AT automatic tuner can tune it on all
bands from 80 to 10M. The wire I used was electrician's
14 AWG copper stranded without tinning. Tinning would
increase losses due to RF skin effect.

Made a test contact, from TX to CA with 100W USB,
report of 5-7 on 20 meters at 2:26 zulu. Not too horrible.

Also found out my Sony TV set radiates white noise on 20
when on but not receiving an active TV channel.

3167. SWR Equation Please

Newsgroup: rec.radio.amateur.antenna

Peter, K1PO wrote:
"---let`s consider the use of the laws of physics and rules of mathematics rather than recalling historical incidents of sloppy engineering."

In the 1955 Edition of "Electronic and Radio Engineering" Terman says on page 76:
"Alternatively, a load impedance may be matched to a source of power in such a way as to make the power delivered to the load a maximum. This is accomplished by making the load impedance the conjugate of the generator impedance as defined by Thevenin`s theorem."

I have never seen any reason to laugh at Terman. He is closer to infallible than any source I know.

Simple differential calculus just gives you the slope of a curve at a point where a little bit of x and a little bit of y become infinitessimal. We don`t need calculus for a steady-state matching problem. It`s true that the rate of change of power output is zero with respect to impedance at the maximum power output point, but that`s what the maximum power transfer theorem tells us. The problem is already solved.

Please don`t reply that non-linearity excludes the radio transmitter from the Thevenin treatment. Radio transmitters put out nice sine waves. They are not allowed to be big harmonic generators.

As for dependent and independent variable mumbo-jumbo, the formulas work in either direction. As Reg mentioned at the start of this thread, the output impedance of the transmitter is subject to operator adjustment through the simple setting of conduction angle. The point is that Reg has some new software that answers some of the questions. More power to him!

Best regards, Richard Harrison, KB5WZI

Pete Holden wrote:
> Does anyone have the equation to calculate SWR from measured forward and
> reflected power levels.

SWR = square root of forward power plus square root of reflected power
divided by
square root of forward power minus square root of reflected power

Example: Forward power = 200, Reflected power = 100

SWR = (14.14 + 10)/(14.14 - 10) = 5.83

Peter is absolutely correct. There's nothing wrong with the theorem except that it's often misapplied. Given a Thevenin source model in which you're free to adjust the source impedance, the source impedance which will deliver the maximum power to any load is zero ohms. Anyone who doesn't believe this is encouraged to try and produce a single exception with numerical values. Peter had left this conclusion as an "exercise for the reader", but it looks like it's going to be necessary to state it more explicitly.

Roy:

Thanks for that. I am sure that you have "done the exercise" and are now convinced of the validity of your claim.

And so here on the NG we can now proclaim that we have the new "Lewallen's Maximum Power Transfer Conjecture", or perhaps Lewallen's Source Impedance Theorem, or whatever... I suppose the "Mathematicians" won't let us "coarse engineers and ham operators" be callin it a "Theorem". At least until the proof is exhibited for all to see and they decide if it is significant enough. Perhaps it will just be treated as a "lemma", or whatever...

BTW... I have often wondered just who is the "Pope" of the mathematicians? Who is the one who allows such results to be cannonized into "Theorems"? Is there a Chief Mathematician? Who? What? I once worked for a Chief Engineer at a company where I was employed, but never saw or heard of a Chief Mathematician to this day. Strange!

In any case, here it is in all of it's glory!

Lewallen's Maximum Power Transfer Theorem states that -

the value of the "internal" impedance of a voltage source required to deliver the maximum power to a fixed load, is...

"ta da"....

ZERO!

A corollary to this theorem, which I am sure is near and dear to Reg Edward's heart, is...

the value of the internal impedance of a current source required to deliver the maximum power to a fixed load is...

"ta da"...

INFINITE!

Let's call this converse to Lewallen's Theorem, "Edwards Theorem" since our illustrious NG poster Reg Edwards has written and provided free "gratis" an excellent software design package which makes use of it.

For those practical lab oriented folks wondering about that latter value of source impedance, you won't find resistors of that value [INFINITE] in your parts bins, not even in the new 604 SMT package, heh, heh...

However, as Reg has noted on occasion, the "plate resistance" of a tetrode is a pretty good approximation to INFINITE. At least, as the engineer said

to the mathematician, good enough for all practical purposes.

and so one might ask of what use are Lewallen's theorem and it's now
celebrated corollary, Edward's theorem?

All of you source designers out there please take note!

And pray tell us exactly... how do these two theorem's help us to design
amps?

Please, there's no need to assign a name to this (although I recognize the spirit in which it's being done ;)). Anybody with even basic technical knowledge can draw a three-element circuit, write the Ohm's-law equations for it, and see the result in a couple of minutes. High school level calculus is adequate to prove it definitively, but elementary algebra and a little intuition is plenty adequate to be convincing.

There are a lot of "theorems", "laws", and rules floating around out there. But too often, the people using them don't have any idea what the limits of their applicability are. When one is misused, you're lucky if the answer is so absurd that it's obviously wrong. Other times you're not so lucky. When in doubt, go back to the basics.

Yes, Peter, I've "done the exercise". I think it was in the early or mid '60's, either when I was in high school or not long after I got out.

Thanks guys,
I've now attached the tapered feed from 20 inch down 10
1/2 inch with a length of 1.25 wavelength after another discussion with
W1VDE Roger,on the end of the tapper I've put a 4:1 1/2 wave balun made of
mini coax,and then fed with 50ohm,no idea what the match looks like,after
this I plugged on my little handie and went out into the backyard held the
rhombic vertical and hit two out of three repeaters firing through trees and
garden sheds.I'm happy it's working,it's very sharp.
Having lots of fun,thanks again,

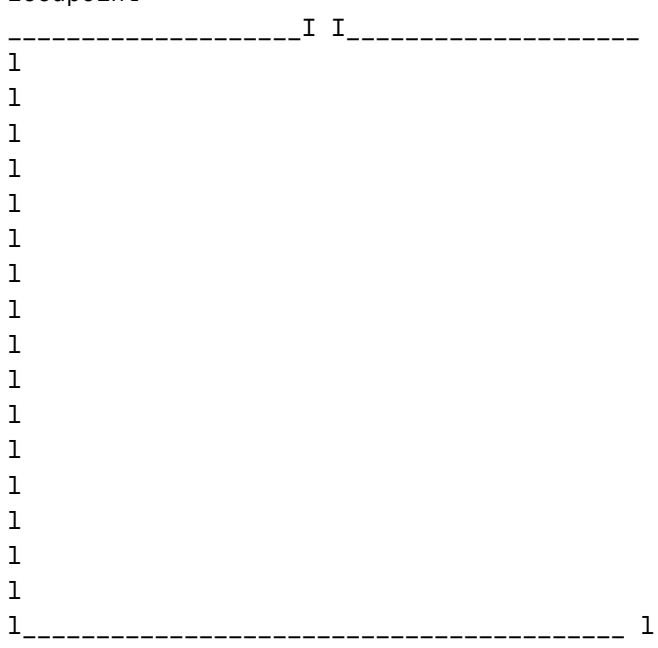
I need to learn something more about the broadband conformal HF FAN wire antennas.

3182. HF Loop Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-16 11:34:09 UTC
From: Big Ben <SPAMSUCKSbigbensblazer@yahoo.com>
Message-ID: <of8j6.12$jR.27705@news.uswest.net>
Source record: 170256

I've seen and read stuff about wire antennas that are basically just a big horizontal loop or square of wire. Ok I'll try to draw it.



Well that took a while. Now the questions. Please base it on 80 meters.
1) How long - total length or if a square, the length of each side?
2) What kind of wire is best to use?
3) Do these have to be a perfect square? I live in a mobile home and would like to mount it above the roof which is 14x67 feet.
4) Will the aluminum siding or rubber coated aluminum roof cause problems with the performance of the antenna?
5) Will this perform any better than a standard long wire? I am in a mobile home park so I would have to use an inverted vee.
6) If this will work, how high above the roof will it need to be mounted?

Thank you,
Ben Lee

Message-ID: <3A8D1761.49834D7C@bloomer.net>
Source record: 170257

According to the ARRL Antenna Book, a full wave loop's lenght (in feet) is calculated by taking 1005/frequency in MHz (1005 divided by the operating frequency, i.e 1005/3.850 = 261 feet total). They show it as a square or even a triangle, so shape may be a bit variable. Of course a square sounds like it would be best, but you can adjust as necessary. It doesn't mention what the feedpoint impedance would be, so I'm not sure if it would best be fed directly with 50 Ohm coax or ladder line with a tuner. If you have a tuner, I would just try it out and see how it works feeding it with coax.

Looking further in the book, I see they feed a loop directly with coax. I can scan a copy of the article and send it to you if you like. Just send your real email address directly to me (I believe it would just be with the SPAMSUCKS removed :))

Roy:

Heh, heh... Roy as you no doubt understand that I am being somewhat fanciful in my characterizations of these "theorems".

Still and all, from recent controversies in our avocation, it seems that simply giving something a name and applying capital letters to it's name can raise the level of it's importance far beyond it's applicability in some folks minds.

Certainly, in recent times, the "Conjugate Match" has been so raised in importance by some as to have reached the status of a religious belief. Of course, I too prescribe to religious beliefs, and I readily acknowledge that there will always be a place in human endeavor for religion and belief systems without a rational basis. However such belief systems are non-scientific and when applied to engineering endeavors they can lead to disasters. Humans simply don't design aircraft based upon the principles of Mohamed's ascent from the Rock, etc... And, like many mis-used religious beliefs, when carried over into all parts of life far beyond their original mission, they can become disadvantageous rather than advantageous.

I believe it was Tom Peters who said... "Perception is Reality"...

and so if, by giving these simple results names such as Lewallen's Theorem and Edward's Theorem, we can create the perception that they are of "great importance", why then perhaps they will become important to people and will be recognized as the useful and applicable results they most certainly are.

It will certainly help to raise them to the level of perception of the "Conjugate Match" so that they can sit with that august concept in a position of equal importance!

Best,

-Peter K1PO

If the full-wave loop is in a vertical plane then the 135' doublet would be preferable. The ground loss in a vertical loop would be greater.

If the loop was in the horizontal plane there would be little to choose between the two except, perhaps, their radiation patterns. But in any case, at the average amateur QTH, there is not a close agreement between predicted and actual HF radiation patterns.

But it should not be a complicated matter to change from one simple antenna to the other. Let us know your findings.

Before reaching conclusions and questioning those conclusions, wouldn't
it be good to say whether the loop is horizontal or vertical? :-)

Why would you want to make the system more complicated and less
reliable Stan?

That is what would happen.

Have you been reading advertisements about traps being especially bad
or something?

The voltages at the ends of a resonant dipole are too high for most
relays to handle. Some sort of bi-stable solenoid with enough air
gap would work better.

My friend, Dave, G3YNH, is constructing a polarisation rotator for a
12 element ZL-special 2M antenna. He is using a gearbox from a
pre-war wind-up gramophone and the motor from a 35mm camera.
The motor runs on ~3 volts and is about 2cm x 3cm. with a 3000:1
reduction gear it can turn 180 degrees in about 30 seconds. It is
powerfull enough that you can't stop it bare-handed even on a
4" diameter wheel. It would certainly work as a conventional
rotator for 2m yagis of 12 elements or less.

The project is near completion and will be on the web when
finished, at

http://www.camuw.demon.co.uk/web_site/g3ynh/g3ynh.html

Not there yet but coming soon!

best

Paul, VK3DDU wrote:
"---next I`m going to put in a terminating resistor and change it again."

The terminating resistor makes a rhombic unidirectional. With an open or a short at the far end of a rhombic, the reflected wave radiates in the reverse direction. With the proper termination, the remaining forward wave is absorbed.

There is no difference in rhombic forward performance when the far end is open, shorted, or matched to a terminating rsistance.

At a European broadcast plant where I worked, we temporarily ran 100-KW transmitters into 10-KW rhombics while we built curtain antennas. Our target was Eastern Europe. Our rhombic dissipation lines soon melted. For many weeks we ran with bi-directional rhombics. When we replaced our dissipation lines with heavier stainless wire we got a flood of protest from listeners in South America. They could no longer hear us. Sorry, but they were in an area claimed by other broadcasters as their targets at the times they were hearing us.

A terminating resistor can make a slight reduction in impedance variations seen at the driven end of a rhombic, but not much. By the time a wave makes a round-trip on a long rhombic there is just not much energy left to affect impedance at the drivepoint. It`s been radiated.

Best regards, Richard Harrison, KB5WZI

Source record: 170172

I don't have the article in front of me but I a while back there was one titled Loop Skywire (or something like that). As I remember, the best configuration was to maximize the area within the loop - which would be a circle. A circle isn't real practical so most use a square or something close to it, depending on supports available. Also, I believe they had theirs cut at 272'.

The other thing affecting this is height above ground - otherwise it becomes a cloud warmer.

I live on 5 acres and have been reading about long wires, long wire V's, rhombics, loops, etc. I figure mulitple wavelengths of wire in the right configuration will beat any triband beam (which I have). One particular configuration I am leaning towards is a switchable V combination so you can get most directions with lots of gain.

If anyone has experience with long wire V's please speak up!

Roy Lewallen, W7EL wrote:
"Given a Thevenin source model in which you`re free to adjust the source impedance, the source impedance which will deliver the maximum power to any load is zero ohms."

Yes, and the load which will accept maximum power from the zero-ohm source is as close to zero ohms as you can get without actually arriving at zero ohms.

The maximum power transfer theorem is still intact despite a reduction to the absurd.

Richard:

Wow!!! What an idea.

Who wants to draw the maximum power from a zero ohm voltage source? Would sort of be like blasting Hoover Dam apart to fill your bird bath! What?

Your comments simply don't make "walkin around" sense over here in source land...

A practical person would not attempt such a thing... unless of course he had an investment in a fuse or circuit breaker manufacturing company!

What?

Richard, come on over to the "other" side with us source designers.

The Dark Side?

You can go back to designing loads anytime, the load designer's union will not disown you just because you spend some time designing sources!

Don't worry, it won't hurt. Heh, heh, I know you'l really like it.

Best,

-Peter K1PO

news:3A8CFC0B.A395544C@ids-spa.it...
> I need to learn something more about the broadband conformal HF FAN
> wire antennas.
>

As a general overview, HF fan antennas installed on Naval ships are generally designed to operate untuned from 2.0 - 6.0 MHz or 2.0 - 8.0 MHz (maybe 10 MHz in some cases) with a maximum SWR of 3.0:1 over the band. Many of the installed fans will have a maximum SWR up to 4.0:1. The choice of upper operating frequency (6 or 8 MHz) is based on the configuration of the HF transceivers used to cover the 2.0 - 30.0 MHz frequency band. Older US Navy transceiver configurations had the HF band segmented into three smaller bands: 2 - 6 MHz, 4 - 12 MHz and 10 - 30 MHz. You will note some frequency overlap. Recent installations segment the bands differently as the transceiver systems are designed to be more broadband.

The HF fan antenna is typically constructed using two fan sections each made with three or four phosphor bronze insulated wires. Each end of the fan is insulated from the ship using delrin insulators. The fans are typically suspended from a main-mast yardarm to a deck level. The fan feedpoint will be located somewhere on the mast near the upper end of the fan. The fan wires will be connected to a single or dual feedpoint. A broadband matching network comprised of high-voltage vacuum capacitors and lowloss inductors (sometimes wound using CU refrigerator tubing) will be used to provide the impedance match.

The fan antenna itself is really designed to couple energy to and from the metal structure of the ship and its yardarms. At lower HF frequencies the fan essentially induces currents in the ship's superstructure so the entire ship functions as the "antenna". Integration of the fan into the ship's superstructure is important and that's why many of these antennas are (were) designed using 1/48th scale brass ship models (1/50th scale for metric).

If you have any specific questions, I would be happy to help.

Try the numbers.

My near short-circuit load makes a lot more sense than your zero-ohm source. I can easily produce a very low load impedance. It is difficult to produce a zero-impedance high-power source.

Hi Peter,

Sorry to have dismissed your academic (or high school) ï¿½tudes, but
they are simply not responsive to my post and of no particular
interest (and already handled better in the classical discussion of
Thevenin). Such ossified discussion is in glaring contrast to how the
Mad Man with a simple pair of dikes could cut to a solution without
all those old wive's tales. ;-)

I especially like each statement you make followed by the reflected
admission of "what?" Your mantra is certainly more entertaining, but
it could use a drumroll from Skitch Henderson's Band. ;-)

Sorry, but John Fakan presented far more compelling, and interesting,
discussion; but his was centered on experience proving theory rather
than conjecture and idle thought ambling through tedious math.

Some people have their minds made up, and closed.

You obviously don't understand the concept of a non-dissipative source
resistance (impedance) Peter.

Some people do.

Those that do, have no trouble understanding the concept of power
being limited without a dissipative resistance being necessary. It's
been explained so many times in so many ways, any further explaination
(especially in the face of 150 line posts) would likely do no good.

With that in mind, threads like this are useless.

Even if he does that, he still has the same choking problems he has
with a trap if he wants to get control voltages to the next section.

A latching vauum relay would work best, but they require amperes of
coil per relay current at 24 volts! Imagine the difficulty in getting
seven or more amperes of control system current past the elements gaps
at each relay, and delivering that current from the house without
excessive resistance in the wiring!

The best solution would be to replace the relays with traps.

Yes, I'm tinkering with one now. I have a three bander (10, 15, and 17 meters). It is about 14 feet in diameter. It is giving me about 3 S-units(on a Yaesu FT-840) forward gain over my 3 band dipole. Right now, it is only about 12 feet high (on my "test" mast)

So far, the biggest drawback seems to be the narrow bandwidth. It works pretty good for $12 worth of electrical conduit (the support structure) and another $15 worth of wire. It is a good receive antenna (compared to dipole), very quiet. Also, it has been a lot of fun to work with.

I am sure a three element tribander is better, but I have a lot of trees, not much room to turn a tribander. Also, I don't want to spend money on a tower. I plan to mount the completed model on a 30 foot guyed TV pole.

Also, I don't know how much better the commercial hexbeam might be. It seems to be constructed of good material. I was curious, and got interested in the idea.

If you have specific questions, I'll take a shot.....

Why would one need to get control voltages to an unused section?

```
\ \ / /
--------- +--------- +---------x---------+ ---------+ ---------
```

You would always have control over the next one that you need to
control assuming you can perform the switching serially in two or
more steps.

When I was in high school and didn't know how to feed a non-resonant
length dipole with open-wire feedline, I put an insulator at each
'+' point above. I had the dipole on pulleys so it was a two-minute
task to add jumpers to change bands to a different resonant-length
dipole. But I guess modern-day hams are too lazy and too spoiled
for something that simple.

I have used a relay suspended in an antenna wire to shorten it for resonance on a higher frequency.

This entails using twin wires (like 22 awg speaker cable) for the antenna wire up to the relay. I used an ordinary 12 volt relay with a single make-break contact rated at 500 volts. Prevent high RF volts between relay coil, core and contacts with a 0.02uF (or thereabouts) decoupling capacitor between each end of the relay coil and and the metal relay frame.

The 500-volt contact rating appeared to be adequate for a 100-watt transmitter.

At the transmitter end connect a 0.02uF capacitor between each antenna conductor and the transmitter or tuner output terminal.

Connect a bifilar choke wound on a ferrite rod, 6" or 8" long, 1/2" or 3/8" diameter to the pair of antenna conductors. The choke can be wound with the same 22 awg twin speaker wire as used for the antenna. Take the other end of the choke winding to the DC relay-operating supply. Include the on/off switch.

Ground one side of the DC supply. I used a spare 12 volt DC output from the transceiver. Make sure no other part of the antenna+relay+power supply can become in contact with ground or a fuse may blow.

Eventually I removed the relay because the relay contact resistance increased and became noisy when receiving on the lower operating freqency.

There are such things as reed relays with mercury-wetted contacts in a nitrogen atmosphere. The between-contact capacitance is very small. But I think the contact voltage and current ratings are low.

There should be no problems running connections to relays through tubular conductors. But still take the precaution of fitting decoupling capacitors at the relay end. Also a bifilar choke to decouple the relay power supply from the antenna system.

Latching vacuum relays capable of holding off several kV are either very expensive or very cheap. If you're lucky enough to find them cheaply, they look like the best solution because they don't have to be energized all the time. Even thin wires would handle the short current pulses required.

However, like Tom I can't see a good way to get the control wires past the first relay, and onward to a second relay farther down the antenna. It has to involve RF chokes, which may have very similar losses to the inductors in traps.

For applications such as converting an inverted-L for 80m and 160m into a plain vertical for the higher HF bands, a relay at the top of the vertical may be a good solution.

Tom: what do you think of using a vacuum relay to band-switch a top-loading coil between 80m and 160m? There's going to be a lot of volts up there...

I once made an emergency 220 MHz antenna by finding a six
inch piece of 2x4 wood, drilled two holes in it to accept 8
gauge aluminum grounding wire, cut one length of 8 gauge
grounding wire to 1/2 wavelength and another piece to 1/4
wavelength. Voila! Instant J-pole after soldering two
alligator clips onto the end of a piece of mini-8 coax with
a PL-259 on the other end. Just slide the alligator clips up
and down the "antenna" and matching stub until the SWR
disappears. Works great.

Hi Richard.
Today I climbed the roof and hit all three repeaters here
in Melbourne,had a report from one station with good comments,I dropped from
1 watts to 100 mils and still fully pegged the device,the antenna is
definitely working,next I'm going to put in a terminating resistor and
change it again.Having great loads of fun,really appreciate the feedback
from you both,there seems to be little known down here on these subjects I
wonder if my wife would mind moving to Europe or the States,,hi hi.
Keep you posted in the future,thanks again I can't get my energy into
this page enough.
Best 73's,
Paul,,,,vk3ddu,,,,,

Just decide before July 1, 2001. :-)

I split the difference myself and went for 3 years, though right after I
did, I saw this one: :-('cuz I paid more.

< ARRL Offers New Five-Year Membership Plan (Feb 9, 2001) -- With a
membership dues increase going into effect July 1, 2001, the ARRL is
offering a special five-year membership plan until then, so members can lock
in at the current, lower dues rates. Effective immediately, current or
prospective ARRL members in the US and US possessions can obtain a five-year
renewal or membership for $146 ($122 for those 65 or older). That's a saving
of $24 ($18 for those 65 or older) from the cost of year-to-year renewal at
current rates! Due to postal considerations, this offer cannot be extended
to those living in other countries. The special five-year membership offer
expires June 30, 2001, the last day the present dues schedule is in effect.
After that, annual dues will increase to $39 for individuals ($34 for those
65 and older). Another option is to apply for an ARRL Life Membership for
$850. Special discounts apply to senior and visually impaired applicants. A
complete rate schedule and application form is available on ARRLWeb.>

I would go on, but this is an antenna group, but I did want to offer the
options that would save hams money.

I went on an informal tour of the Voice of America transmitting site in Delano, CA. They have a RF switchting matrix so that they can route various quarter megawatt transmitters to various curtain arrays. They used pneumatically actuated switches. That way you dont have relay coils burning up from RF induced into the relay control wires. While you won't have that problem if you do it right at ham power levels, it may be a way to avoid having any control wires at all going inside the antenna element tubing, just some plastic hose. I don't know how to build the pneumatically controlled switch. It's just an idea that you might want to kick around.

Because Reg that isn't what I said.
I qualified my statements because you can not make a generality about it.
Most of the time you may be OK, but there is bound to be that occasion when
you are unlucky enough to use some paint with high losses.

Either read what I said Reg or take remedial reading classes, they can help.

Not critical. A circle is best in general, but can be a square,
triangle, whatever to fit the lot.
> 4) Will the aluminum siding or rubber coated aluminum roof cause problems
> with the performance of the antenna?

It will have an effect. May not hurt the performance too bad, but may
effect tuning. This will effect a dipole also.

> 5) Will this perform any better than a standard long wire? I am in a mobile
> home park so I would have to use an inverted vee.

Dunno.. To tell you the truth, I don't see any real difference in
overall general 80m performance between the two on that band. I've
compared them on 75m. Either one will do the job. I prefer just a
dipole because it's less work for the same appx performance. I think the
turnstile is the best "general purpose" antenna for 75/80m myself. It
seems to outdo either one of the others. It's just a set of crossed
dipoles. One antenna I've never had the room/height to try is the
eggbeater. I'd like to try one of those on 80/40 meters just to see what
they do. I think the common idea of a horizontal loop being a super
duper cloudwarmer antenna on 80m is overstated.
I didn't see enough increase over a dipole to really measure in most
cases. "Both at the same appx 35-40 ft level". But when I compared a
dipole to a turnstile, I always saw an increase with the turnstile.

> 6) If this will work, how high above the roof will it need to be mounted?

If you are over metal, as high as you can get it. I'd try to get away
from the metal if at all possible, but if you can't , just go with what
you can do. You may have to tweak the tuning a bit, but it will still
work. I've seen cases of putting wire antennas over mobile homes where
the metal mobile home really threw the normal operation of a dipole for
a loop. Would have to do drastic measures to get it tuned, such as
offsetting the feedpoint a bit, etc. The home acts as a reflector of
sorts. MK

3231. Re: How to measure self-resonant frequency of solenoid

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-17 00:53:24 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <96kj5o$r65$1@neptunium.btinternet.com>
Source record: 170205

Richard wrote -
> A self-resonant coil is a coil without added capacitance in which most
> of the capacitance is of the "parasitic" variety. As such, the lossy
> coil is maximized, the low-loss capacitance is minimized, and the Q of
> the resonant circuit is relatively low.
==========

Rich, I'm afraid you are in danger of becoming an old wife.

The actual value of coil Q is, as you say, its reactance/resistance, X/R. Q depends only on frequency because X and R depend on frequency. Actual Q remains unchanged regardless of the capacitance across it, self C or otherwise. (The between-turns capacitances are negligible. Why ? Because they are all in series across the coil.)

So for a given frequency, actual Q remains at its normal high value even when the only capacitance in the circuit is the coil's self-capacitance.

But what the circuit designer is interested in is EFFECTIVE Q and this depends on what sort of circuit the coil is used in.

If the coil is used in a PARALLEL-TUNED circuit, with a capacitor in parallel as in an antenna trap, then Q' is the normal value of X/R. If the self capacitance and additional capacitance are in parallel with each other there is no reason to suppose circuit Q is any different from actual Q. For the same voltage across the coil its loss remains the same regardless of the extra shunt capacitance.

However, if the coil is used in a SERIES-TUNED circuit the situation may dramatically change. There is a circulating current around the coil and its self-capacitance. The current flowing in the coil is greater than that flowing through the series resonating capacitor. So coil loss is greater than that due just to the current flowing in the main series circuit. Effective circuit Q therefore is then less than actual coil Q.

Let Fself = Self-resonant frequency.

At a frequency F it is not difficult to prove that the effective Q' of a series tuned circuit is given very simply by -

Q' = Q * (1 - k)

where k = Square(F / Fself) and

Q is actual Q = X/R of the coil at the frequency F.

The effective series loss resistance, R', is given by -

R' = R / Square(1- k)

Where R is the actual coil loss resistance.

The effective series inductance L' of the coil is -

L' = L / (1 - k).

It will be seen that when the series capacitance is equal to the stray capacitance, effective circuit Q is half of the coil's actual Q and this occurs at a frequency of 0.707 of the self-resonant frequency.

At the coil's self resonant frequency, circuit Q is obviously zero because the series tuning capacitor reduces to zero pF and there is an open circuit. Also the effective series loss resistance becomes infinite.

When the circuit is series resonant at a frequency of 1/3rd of the self resonant frequency, effective Q is 89% of actual coil Q which is acceptable for nearly all applications.

A series tuned circuit of interest to the antenna newsgroup, where the self-capacitance of a coil can seriously affect performance, is an antenna loading coil. A loading coil is in-series resonance with the capacitance of the short length of antenna wire or rod or top hat beyond the coil. When attempting to increase radiation resistance, as the coil is raised nearer to the end of the antenna its inductance necessarily increases very rapidly. And so does its resistance even for the same Q. Simultaneously the coil's self-resonant frequency decreases. Effective Q falls like a brick. Loss resistance increases much faster than radiation esistance. The coil becomes hot. The optimum coil height on a very short antenna is usually less than 2/3rds of total height. Often on moderate length antennas any additional loss caused by not externally loading the antenna at all is hardly worth bothering about.

Program LOADCOIL examines the effect on radiating efficiency of sliding a loading coil along an antenna. Self-capacitance of the loading coil is taken into account.

Can't figure out how much to delete from the anti-spam so...

Total length is 1005 divided by the frequency in megacycles.

Best wire I've found is insulated #13 stranded copperweld at 16 cents per foot.

Doesn't have to be perfect square. A circle would be best but performance will be good with unequal side length and unequal height for each section.

The aluminum objects might interfere but then again it might act as a reflector and actually help.

It will perform much better than a long wire. Receive noise will be down by about 6-8 db or so.

Mount it as high as practical. But it will work at only 15 ft off the ground.

73s,

Evan

You don't need to. You can lower the antenna and remove the wires when
you change bands.

Or, you can use several expensive vacuum latching relays at each
disconnect point and some sort of polarity sensing to control relays
with the minimum number of wires.

>When I was in high school and didn't know how to feed a non-resonant

>for something that simple.

That's a good solution. He can lower the antenna and move jumpers
everytime he wants to change bands.

That'll get rid of them pesky traps without the complexity and expense
of relays.

There is no way to get them past the relays, unless you use chokes or
more relays to open relay lines!!

>For applications such as converting an inverted-L for 80m and 160m into
>a plain vertical for the higher HF bands, a relay at the top of the

It is. It works well for a two band change in a simple antenna.

>Tom: what do you think of using a vacuum relay to band-switch a top-
>loading coil between 80m and 160m? There's going to be a lot of volts up
>there...

Depends on the power and the antenna impedance. Even reasonably large
vacuum relays are marginal at kW power levels in a dipole at the HV
end. An inverted L makes voltage about twice as high, because it is
half of a dipole.

Derate the power by a factor of four when making the switch from a
dipole to a marconi, all other things equal.

You not only have to have a relay up there, it has to stand-off the
voltage in all kinds of weather.

No thanks! I'll use a trap or stub decoupling.

One S unit on my FT-1000D is one dB at S-1. It's 5 dB at S 7.

It's between 1/2 and 5 dB on my IC-751A's depending on the S meter
areqa you are working in.

How many dB is your S meter at the point where you made the gain test?

Certainly you don't have more than a 3 dB gain antenna there.

No experience with this on 40 meters - but I had it on 2 meters.
Cured it with a big feed thru cap installed in the trunk in the line
to the fuel pump and a .22 mfd across the 12 supply at the radio.
(Actually the .22 mfd cured the noise from the heater blower, but
may have had some effect on the fuel pump noise.)

Hi Tom,

Certainly you have discovered by now that 1 dB of gain in line-of-sight field strength can - under the right conditions - translate into 1 S-unit for a propagated signal. Seeing a 3 S-unit difference when comparing to a dipole in on-air tests certainly does not seem all that unreasonable to me... assuming, of course, he was referring to on-air comparisons of propagated signals and both antennas were of similar heights and in equal ground conditions.

In any event, since the Hex-beam is a take-off of a critically coupled Moxon design, if properly designed and constructed, in my opinion, it should be capable if at least 4 dBd directional gain.

Since an approximate 3 dB reference is easily obtained - by reducing power by 50% - it would be interesting if kazering could perform such (line-of-sight) tests and let us know the results. Of course, for the results to be meaningful, care should be taken to insure that there is no interaction between the antennas under test.

I used a 10 foot piece of schedule 40 pvc, wrapped a length of wire on
it determined from a software calculation for 40 meters, added a
quarterwave cb whip at the top from radioshack, and tuned it with an
automatic tuner. It is almost as good as a dipole.

Dear Chuck,

Nonsense.

1 dB is 1 dB, either through the ionosphere or a big resistor. The
ionosphere, at least at the ERP levels we can muster, is perfectly
linear.

Maybe you read and believed that "junk" in a recent QST article where
some guy (trying to sell his antennas) claimed or implied the
ionosphere was not linear.

The 3 S units can only come from:

1.) Comparing a null of the dipole to a main lobe of the Hex beam

2.) A grossly inefficient dipole

3.) Screwed-up S meters

4.) Drunks or people with poor vision giving signal reports

The Hex beam, at tops, would be about 3-4 dB above a dipole.

Youseem to think the ionosphere or propagation is non-linear Chuck.
That is absolutely not true.

It is the meters and the PEOPLE in the tests that are the sources of
"non-linear" behavior. 3 dB is 3 dB, even through the ionophere.

Yep. However, the manual does include a method to derive pure
reactance. My guess is the only real difference in in the firmware.
All in all, for my use, the 584B was a bargain.

I've noticed your programs greatly overestimate Q in some cases Reg.
Many software inductor programs do so.

That's probably because the software writers think the turn-to-turn
capacitance is negligable, and that shunting capacitance can not lower
Q at a given frequency with all else constant.

Source record: 170124

Gentlemen, I agree.

First, I did not conduct a scientific study. I put the hex up on my trusty ten foot pole and spent several weeks playing on the radio. The dipole was at a height of only about 25 feet at the time.

I agree that the linearity of s-meters is not to be relied upon for station to station comparisons. Alas, I have yet to build the ARRL attenuator project to have a benchmark for scaling my FT-840 meter into db. So I can not tell you how far off the meter is using a readily available benchmark. I am just guessing, but I would bet the $4000 1000-MP is more linear than my $600 FT-840! (And that didn't sound too linear!)

As Tom noted, I found a lot of variability based on how the strength of the signal I was measuring. My "about" 3 s-unit claim is what I noted on very weak signals. When a signal was about S-1 to S-3 on the dipole, I got between S-4 to S-7 on the hex. Also, signal strength reports from my contacts showed differences consistent with this. Again, not accurate scientific measures, but anecdotal. It did not occur to me at the time to modify the power for a 3db test. It will likely take several months for me to rack up enough information to know.

Since the dipole could not be easily moved, I had two directions to work with. Also, my QTH is on uneven terrain. (We are NOT in Kansas here, Toto!) Also, the gain is better on 17 meters than 15 or 10. I am still working on that, but I now suspect there may be interaction between the elements. Still quieter than the dipole, and more effective a radiator. I took the dipole down to use the tree supports(my longest run) for my 80-40-20 inverted V.

I would not be surprised to find that the real gain of my hex is only 3dbd. For me the real story was the rejection from the sides. The dipole, on my terrain, seems to be a real skyburner. I might as well have a vertical. I hear everybody. The hex rejection of signals to the rear seems good too. The differences there are more dramatic.

Chuck, I started out with an intent to build a Moxon. I actually built one for 2-meters.(untested) To build the hexes, I started with a set of Moxon dimensions, then spent entirely TOO MUCH time pruning and testing. I am now

motivated to buy EZNEC.......

Remember the efficiency of such an antenna is always lower than that
of a similar-length antenna with properly placed conventional
lumped-loading, assuming the inductor is constructed in a somewhat
reasonable manner.

Linear loading saves you the trouble of adding an inductor and makes
the antenna "slim", but the tradeoff is reduced efficiency.

Hey, as you probably have already surmised...

I don't belong to the church of Dissipationless Resistance, and the pastor of my own church [The church of "All Resistance is Futile".] forbids me to attend any of their rituals.

As an ordained priestess, she told me that I'll go to Hell if I attend those rituals!

I guess we'll just have to agree to disagree and let everyone go to Hell thier own way. Thank God for the US Constitution!

I hope Johann Frederich Ohm is not turning in his grave. "Dissipationless Resistance" indeed. RIP dear Johann.

BTW... speaking of adjectives applied to the noun "resistance", I'm curious.

Even though I am not allowed to attend your services, I have often wondered, in your church, what name do y'all have for the value of the voltage across a flashlight battery divided by the current into an HF power amp at sunrise?

FlashAmp Resistance perhaps?

Is it dissipative or not? What?

Best,

-Peter K1PO

P.S. Stealing a catchy phrase from Mark Twain K5MT, I'd like to state that, "the above was writ Ironic". Was Mark a 5-lander or a 4-lander?

The SWR of my D-130 is a flat 1:1 accross the 2 meter band.
Everything below that has SWR except for the top whip and coil frequency.
You can use other resonators like Hustler or a full size hamstick for other
bands.

Try removing the 6m coil and whip and see if the 2m SWR improves.

That would be a "ROMBIC" antenna.
But I dont think you will get one to fit into you attic.
You might be able to use a large multi loop antenna but it would be
directional.
Most likley antenna for your attic would be a dipole type.

Hi

I have a question regarding a earth mat.
I think I know how to test a single earth spike, a good resistivity
are under 10 Ohm, if you take the measurements from 10 and 20m from
the spike.
But how do you test a complete earth mat say 70 squere meters used by
a HF antenna system?

Any help ??

Regards
B Owen

Peter, the Z0 of a transmission line has a dissipationless resistive component. The IEEE Dictionary says that resistance is "the real part of impedance". Dissipation is not required in that particular definition. The IEEE Dictionary also says dissipation is "the loss of electric energy as *HEAT*". According to the IEEE, a resonant antenna is nearly a dissipationless resistance. The 50+j0 ohm point in a transmission line is at a nearly dissipationless resistance point.

> That is absolutely not true.

In my mind, ionospheric linearity is not the issue here - rather, signal scatter / path attenuation is. My experience suggests H-plane beamwidth is a more significant factor on the success of the propagated signal. Apparently, the more concentrated the lobe is in the H-plane, the less will be the scatter / attenuation that occurs. I would suppose the H-plane beamwidth of the Hex-beam - or beams in general - is signigantly narrower than that of a dipole.

Hi kazering,

I am quite impressed with Moxon's work...

While pruning and testing is certainly educational and perhaps entertaining, it can be quite labor intensive and time consuming! Modern tools such as modeling software and hand-held analyzers are a huge improvement over the stuff we had to work with 40 years ago... hi. I'm sure you will find EZNEC to be of much help.

Peter, K1PO wrote:
"---I`ve found that Carolina Power and Light seems to make a pretty good zero ohm source."

Carolina Power and Light works to appear as if their source has a very low resistance. To do so, they perform voltage control at a local level. Tap changes are used at substations to raise and lower voltages supplied to customers to compensate voltage variations resulting from loss in generation and distribution apparatus.

Overload your circuit severely but just instantaneously. You`ll see the lights dim for that instant.

Peter, K1PO wrote:
"I don`t belong to the Church of Dissipationless Resistance."

Dissipationless resistance is a coined phrase, not an article of faith.

The most simple example may be a silicon diode in series with a 100 watt, 120 volt a-c lamp.

A perfect diode allows current only on half of the a-c alternations.

A real diode has almost no reverse current. Its forward voltage drop is a fraction of a volt. So, its loss is less than a watt. Compare this with an ordinary resistor which would dim the lamp by the same amount. A practical resistor would get plenty hot dimming a 100 watt lamp by the same amount that a cool diode would do.

The apparent brilliance is identical whether produced by a series resistor or by a series diode. It is fair to characterize what is happening in the diode as a near dissipationless resistance when compared with what is happening in a resistor that gets plenty hot.

Best regards, Richard Harrison, KB5WZI

Exactly. I'm sure the Federal Government didn't place the T2FD's they used in service without such an evaluation and operational testing. I don't think anyone believes they're anything they really aren't. Of course there are better choices for most amateur uses. Thanks.

Tom wrote:
"What is the most powerful AM antenna I can build?"

Tom also said he had a 3rd floor attic with lots of space. Probably not enough space for a directional antenna other than a loop in the medium-wave band.

Housewiring in an attic may carry interference to be avoided. It is preferable to have an antenna sited away from interference and have the signal wired to the receiver with balanced or shielded cable.

If the antenna can`t be placed in the clear, a loop has the possibility of nulling out some of the noise and interference.

Signal strength is usually adequate in good receivers. Preamplifiers amplify noise along with the signal and usually don`t help. Preselection can help when strong local stations may overload a receiver tuned to a distant station near the frequency of a local.

Armstrong discovered regeneration was an effective way to sharpen bandwidth and gain of a receiver nearly 100 years ago. Controlled regeneration is still used in active antennas and preamplifiers.

The easiest thing to try after a random wire is a large external tuned loop antenna.

Best regards, Richard Harrison, KB5WZI

Which is the conclusion that I drew from my time as an emergency planner.
In a disaster that covers any large area or region it takes time, and lots of it, to get even a wellplanned relief effort to the people who need it worst. Ask the people in the area of Homestead, Florida. There are *lots* of things that escape the eye of planners, no matter how thorough they think they are.
In the Loma Pietra (San Francisco) quake the TV stations had built a huge hardened tower, and had hardened their station plant until they were sure that it would survive. But the diesel fuel tanks for the generators rolled off their cradles.......

Cecil:

I beg to differ with the loose lexicography promulgated by the IEEE's poor excuse for a dictionary!

Excuse me, but describing a thing as a "dissipationless resistance" is sort of like those other "silly" combinations of adjectives and nouns such as "jumbo shrimp", "military intelligence", etc...

Come on, get serious, resistance cannot be simply defined to be the "real" part of an impedance. One often finds that resistance is the real part of an impedance, but not always. Defining it that way is the same as saying that gold is the real part of a dollar. What?That is a necessary condition for something to be called a resistance, but certainly not sufficient. The real part of an impedance might be a resistance, but then again maybe not.

The necessary and sufficient condition for a thing to be called an electrical resistance is dissipation pure and simple.

To be an electrical resistance a device must convert all of the electrical energy presented to it into a completely different form of energy. Since all of us non-relativistic hams and engineers believe that energy can neither be created or destroyed, the dissipation of electrical energy simply means the conversion of electrical energy into some other form. Usually heat, but it could be radiant or kinetic energy, etc..

That's what an electrical resistance does pure and simple. It dissipates electrical energy. Nothing more nothing less! Deal with it.

I simply cannot agree to such a misuse of the term resistance as the IEEE Dictionary tries to pass off in it's offhanded reference to some vague concept called dissipationless resistance. And neither should anyone else. It's sort of like the ignominity we English speakers have allowed to be bestowed upon that once wonderful word "gay". Gay has now been completely usurped by common use and today folks think of something completely different whenever it is used.

I believe that what y'all [Including the IEEE] are calling dissipationless resistance, is properly called "effective resistance" or perhaps by another new word such as "effistance" or some other such new word, in order to avoid applying an ill-chosen adjective to a well understood concept. What y'all need to do is to apply some other such phrase or word to your unecessary new concept, one which does not prostitute the true meaning of the word resistance by implying that there is some kind of dissipation that can be dissipationless!

BTW... as sources go...besides Carolina Power and Light having nearly zero Ohm sources, most Operational Amplifiers come pretty close to a zero output resistance, and those OTA's or Operational Transconductance Amplifiers come pretty close to an infinite output resistance.

And what about all of those other new things and concepts invented since Dr. J . F. Ohm passed into that big lab in the sky.

I mean those devices and concepts with names such as: transconductance, transresistance, gyrators, isolators, circulators, current conveyors, nullors, norators, magic tee's, GIC's [Generalized Immitance Converters] and such. Why... they all got brand new names. The folks introducing those new concepts didn't try to mess up perfectly good meanings! What?

I think that you guys just don't have the "guts" or persistance to invent and promulgate a new name, and so you try to pass off your so-called new concept by slinging improper adjectives at a perfectly good word, "resistance".

So there... here's my challenge to ya'll!

Why not give a brand new name to the "dissipationless resistance" instead of messing up a perfectly good name and concept?

And while you'r at it, stop using the maximum power transfer theorem backwards!

-Peter K1PO

I bet it didn't show any Public Safety dispatch centers at work either.
And believe me, that wasn't just another day at the office for them
The "action" shots are what draws audience attention, the helicopter
rescues stranded people on rooftops, etc, not someone talking or typing
into a radio. A Morse code key might draw attention, though. :-)
Ham radio doesn't ofgten get much good press. I guess the folks in
Newington are too busy congratulating each other.

Dick

[snip]

Tsk, tsk...

No! I wholeheartedly disagree!

It is not fair to charcterize a diode as a resistor!

Why not characterize an airplane as a train? They both can be used for transportation.

A light bulb can be dimmed by any number of devices including a passive LC tank circuit, which will not even get hot, but we don't characterize them all as resistances. What?

Come now... that kind of loose analogy and hocus pocus can be passed off to lay people and CB operators, but... not on this NG.

Best,

-Peter K1PO

When Peter wants to slow the engine down in his Toyota, he applies the
brakes.

That's much better than liting the power of the source.

When you and I drive, Cecil, we shift gears so the engine's available
power is matched to the load.

Peter just leaves it in high gear... because while we try to match the
dissipationless resistance of the source.... he matches the friction
of a needlessly high power source.

> an impedance, but not always.

Who said it was "always"? That's just one of two definitions of resistance
but the point is that it is one of the two *scientifically acceptable*
definitions of resistance. A resistance may dissipate energy as heat
but it is not required to do so. A resistor has dissipative resistance
but resistance doesn't require the existence of a resistor.

> The necessary and sufficient condition for a thing to be called an
> electrical resistance is dissipation pure and simple.

Nope, it is not necessary for resistance to dissipate power. Definition
(A) is for dissipative resistance. Definition (B) allows for a
dissipationless resistance. The IEEE dictionary says that the two
definitions are NOT equivalent and instead are supplementary.

> To be an electrical resistance a device must convert all of the electrical

> all of us non-relativistic hams and engineers believe that energy can
> neither be created or destroyed, the dissipation of electrical energy
> simply means the conversion of electrical energy into some other form.
> Usually heat, but it could be radiant or kinetic energy, etc..

Nope, the IEEE dictionary says "dissipation" is limited to heat energy.
Radiation is NOT dissipation according to the IEEE.

> That's what an electrical resistance does pure and simple. It dissipates
> electrical energy. Nothing more nothing less! Deal with it.

But that's not what a resistive Z0 does. That's not what a resonant
antenna does. According to the IEEE dictionary, RF radiation is NOT
dissipation. Heat is dissipation.

> I simply cannot agree to such a misuse of the term resistance as the IEEE

The English language has lots of words with more than one definition.
"Bus" is one of them and so is "resistance".

> Why not give a brand new name to the "dissipationless resistance" instead of
> messing up a perfectly good name and concept?

Why not just accept the second definition of resistance as presented in
the IEEE dictionary? Would you have us rename a computer bus to something
else because it doesn't have wheels?

Yes, I thumb through Moxon's book quite often. I also enjoy
the many articles from W4RNL, on moxons and other topics.

I have a MFJ-259b (borrowed), it helped with SWR
adjustments. I went through two sets of batteries. I am
sure EZNEC will be fun too. I sure did get tired of running
back and forth, raising and lowering, ad infinitum.....

In the end I may fall back to a moxon, on 10, 12, and 15
anyway. I think the support structure will be too large for
a moxon on my site on 17 and 20 meters. I'm, too cheap to
buy a decent beam....hi....

Have you any experience using a moxon?

Thread:

Q is a somewhat nebulous concept. Quality is always subjective I suppose.

Q has several definitions in the literature and one has to make sure what definition is being described and discussed before entering upon a measurement or calculation of its value.

The "Q" found in the electrical and electronics literature refers usually to the "quality" of energy storage devices.

If energy storage devices were perfect we wouldn't need Q. If companies were honest we wouldn't need a Better Business Bureau.

Q then arises only because of secondary or undesirable effects.

In other words, in a perfect world, Q would be infinite and we would not be discussing it.

There is a reciprocal concept often called "dissipation factor" sometimes labeled with the character "d", usually defined such that dissipation factor d = 1/Q.

In a perfect world d is always zero and again, we would not be discussing it.

Any devices capable of storing energy can have a Q. A capacitor [condenser] can have a Q. An inductor can have a Q. A tuned circuit, which is a combination of an inductor and a capacitor can have a Q.

Some think that Q or d is a constant. Because it arises from secondary or undesirable side effects Q or d is not a constant and varies with other parameters, such as frequency, current levels, etc...

I believe that the "best" definition of Q for any energy storage system and the one that most often corresponds to the formulae found in most references is:

Q = Energy Stored Per Cycle/Energy Dissipated Per Cycle

Simple calculations for an inductor L having a parasitic resistance equivalent to a series resistance R then result in:

Q = (2 pi f L)/R, with similar formula for a capacitor with an equivalent parallel conductance G, etc...

The problems in finding simple formulae and or software algorithms to calculate this Q arise in calculating the values of L and R from first physical principles. For instance the parasitic resistance varies with

frequency due to skin effect, and the equivalent L varies with frequency because of the effects of parasitic interwinding capacitances, all of which are functions of the physical geometry of the devices, etc...

How are we to believe in any computer program that purports to calculate Q?

We could ask the programmer to share his/her formulae and code with us so that we could understand what factors enter into the calculations.

Reg? Care to share?

But clearly, if we are from that great State of Missouri in the USA, "the show me State", we should compare the computer program output to laboratory measurements of Q.

How are we to do that without a Q meter at our disposal?

And... even if we have a Q meter, whose design is it? And how does it measure Q?

Was it made by Boonton, made by HP [Sorry Agilent], or Marconi, or Wandel and Golterman, or Siemens' or what...

Reg, care to share with us which instruments you have used to develop the experimental measurements that you have used to validate the formulae and algorthims in your programs?

Thoughts, comments?

Peter K1PO

A few comments encompassing several responses already posted to this question:

I've been using a Traffie HexBeam (HX-5B) for 10 months now, and haven't experimented with any homebrew versions yet. If I were building my own, however, I think I'd use separate feeds for the multiple driven elements (on a multi-bander) and mount a coaxial switch at the top of the tower. The current commercial design involved a lot of trial-and-error work to optimize forward gain, f/b, and SWR across all of the bands. I suspect that one could avoid all that with the separate feedlines, but there would undoubtedly be interactions among the elements anyway. Perhaps someone who has modeled such instances could comment on that.

One response mentioned a narrow-banded characteristic of his home brew effort. With my hexbeam, it is NOT narrow banded in terms of SWR, but is perhaps in terms of f/b ratio and forward gain. The SWR is rather flat across all five bands, but the f/b ratio deteriorates noticeably on some of the bands as you move up the band (it's optimized for f/b at the low end). Yes, I know that a resistor would also have a flat SWR across the bands. If you'd like to compare your yagi against my beam on the air, let me know and we'll set up a schedule.

You can settle the "how many dBs per S-unit" argument for your particular receiver by buying a step attenuator like the MFJ-762 or building your own. On my TS-850S, I found that an S-unit was anything from 3 to 7 dB. Clearly, the S-unit scale was laid out for appearance and had little to do providing accurate measurements. With the step attenuator, you can also measure the f/b ratio with reasonable accuracy, provided you have a stable signal to listen to.

The other thing I learned from observing the f/b ratio of this antenna is that observed f/b did, on occasion, measure far higher than it should have. In some cases, with stable signals, I see f/b ratios around 30 dB, while around 10 dB is the normal measurement. I have no reason to believe that has anything to do with properties of this particular antenna design, and suspect that one could observe the same variation with other directional antennas, but I have not attempted to do that. Maybe someone can explain the mechanics of such results.

It would be interesting to hear about experiences in homebrewing a hexbeam for the 40 meter band. I haven't seen the Traffie version of the 40 meter hexbeam, and I wonder if the mechanical design of the higher frequency models scales up with little change.

From: Chris McGowan <c279m@yahoo.com>
Message-ID: <qSDj6.718$IV6.58926@news1.news.adelphia.net>
Source record: 170158

Hello,

Does anybody have any ideas on antenna mount options for a dual band 2m/70cm antenna on a 2001 Jeep Cherokee? I currently have a nice dual band Diamond antenna about 50" in length that I used on my last car with a MFJ multi-angle trunk lip mount. It looks like right now I have 2 spots. The first would be to attach to the side of the rear hatch as high as I can go or to the front hood. If I go with a roof install, I would be to high for a garage.

Second, does anyone have experience with an overhead storage shelf for trucks, specifically the ones that attach to your visor mounts? I was wondering if they are strong enough to hold a rig. My rig is a Yaesu 8100, not too heavy. Thoughts, comments on this type of mounting?

Thanks

Chris

The solution is to run it from an external battery that will fit
in your pants pocket - one like the YUASA NP2-12 (12v 2ah).

3286. Random Length Wire Antenna Question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-18 00:07:19 UTC
From: "Rex Klopfenstein, Jr." <rklopfen@wcnet.org>
Message-ID: <3A8F1236.54570292@wcnet.org>
Source record: 170159

When the weather here get warmer I am planning to install a wire antenna. I can run a wire 56 feet (maybe 80 feet if I work a little harder--have to put up a mast). This antenna will run from my house to my garage, my radio will be in the basement of the house. I plan to install a good ground (about 6 feet from my transmitter). I would use a dipole but getting the feedline back into the house is a problem, it would drop right in the middle of the backyard.

I have several questions. One is the RF that will be present inside my basement using a random length antenna. How can I reduce any RF in my basement. I will be using an MFJ antenna tuner that supports wire antennae. I would like to put some sort of lightning protection outside of the house for the lead in wire, I haven't been able to find anything listed in the usual catalogs.

Anybody had any experience with an end-feed Zepp? I have a coil of 450 ohm parallel cable (looks like large tv twin lead with windows cut in web), will that work as a feed line. Doesn't the end-feed Zepp introduce RF into shack (high voltage at transmatch).

3287. Re: Ferrite Core Help

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-18 00:19:36 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A8F1518.25149AFD@eznec.com>
Source record: 170161

The angle of the impedance (that is, whether it's resistive or reactive) doesn't matter as long as it's high enough, unless enough power is involved to cause unacceptable core heating. (I've probably said this a dozen times on this newsgroup, but apparently people either don't believe me or they're just ignoring me, since statements like Cecil's keep popping up.) The materials that give you the most impedance at HF are primarily resistive over most of the HF range. Type 73 material is an example. It's a very good choice for this use, and above about 1-3 MHz, its impedance is primarily resistive. This is actually an advantage, because the impedance stays more or less constant for several *decades* of frequency. If it were purely inductive, it would increase linearly with frequency until it approached self resonance, then decrease above that. A good model for the impedance of a ferrite core is a parallel RL network. For 70 series ferrites, R equals Xl at about 1-3 MHz. You can see that at higher frequencies, the contribution from the L becomes less and less significant, so it looks more and more like a plain resistor as frequency increases.

What you need to do first is get the impedance per turn squared for your particular core at the frequency of interest -- which is actually what your question was. You can get this from either the Amidon or Fair-Rite web sites. Don't use the low frequency Al value -- it won't be accurate at HF. (Type 73 material is a Fair-Rite designation, and it's sold by Amidon among other retailers.) Alternatively, you can measure it with an impedance meter or antenna analyzer. It'll probably be lowest at 1 MHz, so use the impedance at that frequency. The winding impedance appears in parallel with the source and load, so you want it to be higher than the source/load impedance to minimize the disturbance on your system. Cecil suggests a minimum of three times higher, but it depends on the application. I like to use 5-10 times when possible. 3500 ohms (5 times 700) might be difficult at the upper HF range because the maximum amount you can get is limited by the stray shunt capacitance of the winding. But at 1-10 MHz it's probably possible. To get 3500 ohms, divide 3500 by the impedance per turn squared from Amidon or Fair-Rite, or your single turn measurement. The square root of this is the number of turns you'll need for the 700 ohm winding. For example, if the core gives you 20 ohms per turn squared, you'll need sqrt(3500/20) ~ 13 turns. The 75 ohm winding would then be 13 * sqrt(75/700) ~ 4 turns. You might want to fiddle the number of turns on the high Z winding if you need a more precise impedance ratio. You can also solve this problem beginning with the 75 ohm winding instead of the 700 ohm winding -- you should get the same result.

Sorry, I brain-farted. Somehow I missed the ferrite type 73 part
and assumed he was making a conventional transformer out of
something like #2 material.

Nulls are the hardest things to predict for any antenna, because they occur when the fields from all the parts of the antenna -- and, in the real world, also the fields reflected from everything else -- all sum to zero or nearly zero. (I like to compare it to subtracting a million from a million to get zero. It doesn't take much of a percentage error in either quantity to have a profound effect on the result.) It only takes a tiny change in one reflection to move a null a few degrees, or change its depth by 20 dB or more. If you compare antenna patterns measured in a more-or-less real environment to ones predicted by a modeling program, you'll generally find that the pattern shape, forward gain, major lobe widths, and most other features match quite well. But nulls often don't. And even in the ideal environment of a modeling program, you'll often see nulls which vary considerably in depth as a function of elevation angle. So I'm not surprised at the differences you see.

Describe the configuration of the loop you want to use. 1 wave lengthor
something else?Horizontal or vertical?
I have a 160 meter 1 wave length horizontal loop up 45 feet in an odd shaped
rectangle. Not the best choice of shapes, but the best I could do. I'm feeding
it with 100 feet of 300 ohm twin lead to a remote balun, then 5 feet of RG-8
coax to my FT-920.The built in tuner tunes 160 thru 6 meters. This antenna does
a fairly good job comparing to my 80 thru10 meter parralle dipole at a similar
height, and to my 10/12 meter vertical. Each antenna has its time when it does
better than the others. But for an all around all band antenna I really like
the loop.Simple, cheap, and does a reasonably good job. It does take some work
to puup 540 feet of wire though. However you can make it as long as your lowest
freq. 73 Rob

I don't like the term "dissipationless resistance". The reason is, I think, sort of like the reason I didn't put the "Mr Yuk" stickers on bottles containing obvious poisons when my kids were little -- I figured they'd interpret it to mean that anything NOT having a sticker is ok to drink.

There are lots of electrical and electronic quantities that have dimensions of resistance and units of ohms but don't convert power into heat. For example, the impedance of free space, or more generally the ratio of an E field to an H field. Anyone using feedback amplifiers sooner or later encounters trans-resistance, which is the output voltage divided by the input current. This has the dimensions of resistance. The impedance of a transmission line is a familiar example. A resistor is a physical device that does turn electrical power into heat, but I don't see why we have to make a special category of "dissipating resistor" for it.

"Dissipationless resistance" is, I suppose, descriptive enough. But I see potential for its misuse and misinterpretation. Do all resistances now have to fit into the binary pigeonholes of "dissipative" and "dissipationless", or do we need more adjectives yet? Is trans-resistance dissipationless? How about the dynamic resistance of a diode (defined as the inverse of the slope of the I-V curve)?

Peter, K1PO wrote:
"The real part of an impedance might be a resistance, but again maybe not."

A resistance is a voltage to current ratio.
It has one further qualification.

No dissipation is necessary in a resistance. Dissipation is necessary in that class of resistance called a resistor, when power flows through the resistor.

A resistance is a voltage to current ratio in which the current is in-phase with the voltage as in a resistor or a radio transmission line excited with an energy surge. This is the one further qualification.

Dissipation or disposition of the energy making a ratio called resistance is immaterial to the status of the in-phase ratio of voltage to current called a resistance, or to its definition as a resistance.

Peter, K1PO wrote:
"A light bulb can be dimmed by any number of devices including a passive LC tank circuit, which will not even get hot but we don`t characterize them as resistors."

Well, L and C are reactances which can inhibit current. Pure reactance consumes no energy. It only stores energy for a short while. As L and C produce opposite phase rotations of 90 degrees each, their effects subtract when used in series combination to inhibit current in a circuit. If the two different kinds of reactance were of equal value and connected in a series circuit, they wouldn`t inhibit current flow at all.

Pure reactances produce no heat at all while inhibiting current. They normally give back all of the energy they accept from a source to the circuit within a complete cycle.

Pure resistances may or may not produce heat while inhibiting current. If current is inhibited in a lossless transmission line by the line`s surge (characteristic) impedance (a resistance because the voltage and current are in-phase), no heat is produced. If current is inhibited in a resistor (a different form of resistance) the energy consumed (converted to heat) is the product of the voltage across the resistor and the current through the resistor.

Richard:

I am afraid that you are wrong here on a few counts. I guess you can be forgiven, since an unauthoritative IEEE publication has apparently legitimized a bad usage of some terminology and you have just innocently picked up on it. Who at IEEE was/is responsible for this terrible work? Dissipationless Resistance. Can you find out the specific author or authority for this article and piece of work? I'd like to know? What was/are his qualifications? Where did he/she get her electrical training? Probably a "Computer Engineer" or some such...

First... there has already been established a common usage for the ratio of E to H in free space and of V to I on transmission lines.

On transmission lines and it free space this has long been called the "surge impedance" or "surge resistance", NOT dissipationless resistance. This well established usage of terminology goes back almost a century.

"Surge Resistance" or "Surge Impedance" is a well known and consistently used term. Dissipationless Resistance is not! It has apparently only appeared since the publication of that terrible IEEE Dictionary!

Your usage and the usage of the so-called IEEE dictionary is not consistent in this respect.

Please make use of the older established usage of "surge resistance" before "just inventing" a new term.

BTW... The ratio of any old voltage to any old current is just that... a ratio of voltage to current, nothing more nothing less.

Why dignifiyt it by calling it a resistance or anything else for that matter.

As I asked further up the thread, what would you call the ratio of the voltage across the terminals of a flash light battery in Paris, France, to the current through the finals of an HF Amp in Burlingame, CA? What? Is that FlashAmp Resistance...

You guys are carrying this terrible IEEE Dictionary dissipationless resistance "mistake" too far...

Enough is enough, now as my Mom used to say, "just stop it, before you put someone's eye out!"

Best Regards,

-Peter K1PO

Peter K1PO wrote:
"It is not fair to characterize a diode as a resistor."

I called the diode a "dissipationless resistance", not a dissipationless resistor (there is no such thing). I didn`t call it a resistor because all resistors convert the energy they accept into heat instantly. Resistors don`t store electrical energy, it undergoes instant conversion.

A resistor is one type of resistance. Not every resistance is a resistor.

A diode used to inhibit current has insignificant energy storage as it is not using reactance to limit current. Voltage and current are in-phase. Power loss in the diode is insignificant, so there is no significant resistor there. The diode is acting as a dissipationless resistance, not as a resistor.

Tom, as a non-software writer, please tell us what YOU think.

In your reply could you be quantitative and include some accurate numerical information? Otherwise words like "overestimate" and "negligible" have no meaning.

By the way have you ever previously come across the formula relating Q', L' and R' for series resonance to the corresponding parallel resonance values, which I gave on my previous posting to this thread.

I see what he might have been saying, but that has nothing to do with
the problem.

The Hexbeam just isn't directive enough to have that problem unless
the error was introduced by making the dipole have a null in the
direction of the arriving signal in the test.

Sometimes people get unrealistic gain results by comparing in the null
of one antenna to another. I pointed that out.

Of course that is a common error.

More than likely the errors are rooted in many things, but the S meter
is a prime suspect since most are very very poor at the low end of the
scale (which is where he measured).

I use 73 material in low power applications at HF, for the reasons Roy
gives above.

I use lesser ui cores like 65 material for high power (flux density)
applications at the same frequency range, because they look more like
a pure inductance and so they heat much less (even though I have to
use a taller stack and more turns to get the same Z magnitude).

As Roy says, I care less what part is reactance and what part is
resistance, as long as the impedance is high and flux density low.

Roy also makes a good point than many people miss, the higher
frequency impedance is nothing at all like the low frequency
impedance...so don't just pick a high ui at dc and expect good results
at 2 MHz or more! Most higher ui cores actually provide LESS impedance
at high frequencies than lower ui cores, and then you wind up using
more turns and reducing bandwidth (and power handling). Look at the
impedance at the operating frequency.

My Beverage transformers (and transformers in my receiving
splitters/amplifiers, etc.) are all a 73 material binocular core that
is about 3/8 inch thick, 1/2 inch wide, and about 1/2 inch deep.

Binocular cores allow you to keep most of the copper inside the core,
so impedance is maximized for a given amount of stray capacitance. The
broadband performance is excellent, since stray C is minimized.

73 works well in low power applications or even at high power in
applications where flux density is low. I've found 73 to be
unacceptable in choke baluns at the 1500 watt power level, especially
if common-mode voltage across the choke is high.

When I measure the Q of an inductor with nearly zero turn-to-turn
spacing, the Q can easily be half or less what it is when the turns
are spaced one wire diameter.

When I look at "programs", they almost always show the opposite.

I can design RF inductors using software that have Q's in the
thousands, but the highest I have ever measured is in the 800
range!!!! Those are generally large tank coils used in high power
transmitters.

I tried to do a notch filter for 160 meters, and the inductor Q is
what made the project not "do-able".

Of course if I used software inductors, it would have worked like a
charm. IMO, the BBB ought to put out a consumer watch for inductor Q
software programs.

Hi Peter,

I have a waterwheel with water spilling ove it, and I am extracting
power from it (through a generator if you like).

I do a load-pull on the wheel, and I find at a certain RPM I get a
certain torque where horsepower is maximized.

To extract maximum energy from that wheel, I must conjugately match
the load to the wheel. The wheel behaves exactly like a "resistance"
is in series with the "voltage", yet nothing is dissipated.

If I put a generator with a non-feedback field winding on that wheel,
I'll get maximum power at a certain load resistance and it will behave
exactly like a resistance is in series with a source voltage.

A switching power amplifier does the same thing, as does a switching
supply. I can easily conjugately match a PA to an antenna and not burn
anything up...and have an efficiency more than 50%.

It's unfortunate they didn't pick a different word to describe
dissipative and non-dissipative power-limited "things".

(What do you do with the body? Did you put it where I told you?)

Peter K1PO wrote:
"Surge Resistance or Surge Impedance is a well known and consistently used term. Dissipationless resistance is not!"

Beg to differ. I`ve heard it used for well over 50 years. Dissipationless resistance is a foregone conclusion, given resistances which are not resistors.

Terman was president of the IRE (a predecessor of the IEEE) in the era when he was publishing and perfecting "radio Engineering". That was long before he invented "silicon Valley". Terman says in "Radio Engineering", copyrighted in 1932 and 1937 (mine is the second edition) on page 698: "The characteristic impedance (of a transmission line) is determined by the line construction and at radio frequencies can for all practical purposes be considered a resistance defined by the equation Zo = Square Root L over C ohms." No dissipation there. Only L and C are involved.

When you have resistors, which are a type of resistance and which dissipate, and you also have free-space resistance, characteristic resistance of a transmission line, antenna radiation resistance and other resistances (not resistors) which don`t convert electricity into heat, you can surely catagorize resistances into resistors and into non-dissipative resistances. That is what the IEEE wisely did.

I don`t think an additional name is needed. I`m still sore over calling the perfectly descriptive cycles per second "Hertz".

Best regards, Richard Harrison, KB5WZI

Looking for a MultiBand 20-15-10 beam type antenna.

I live on the Eastern Shore of Maryland and we at times sustain Hurricane force winds and intermitant gusting to 90mph at different times of the year. I've been using wire and vertical antennas for years. I finally have the money to put up a beam. I already have a heavy duty 38' tower and just got a good deal on a Hygain rotor.

I've look ed at them all I really like Force12s. I don't know if I can spend that much. I looked over the Cushcraft catalog and like the lightweight 'SKYLOG ASL2010 or the MA5B.

Anyone out there in digitland have any realtime experience with Cushcraft. I know there's alot of A3S users around.

Thanks if you could reply!

Hi.

I am thinking in using a 7,5 meter vertical radiator as a multiband vertical. It can be "tuned" (I will say "adapting impedance") with a remote tuned L network placed at the feed point.
My first idea is using three isolated radials 7,5 meter each. The feed point is about 5 meter up the ground.

I think this monster can work between 7 to 28 MHz, also for SWL receiving .
Any ideas about it? I am not sure about radials counterpoise.

I worked 20 years with quarter wave verticals with isolated radials.

As I was reading the SWR and impedance of my antenna on my MFJ-259B, I start to wonder,

1. Does SWR even matter for reception? Now correct me if I'm wrong, since most radios have 50ohm impedance, as long as I got 50ohm impedance at a frequency on my antenna, I would get the best signal on that frequency regardless of what the SWR is at that frequency, right?

2. My magnetic 2m mobile antenna on my car is not really connected to the car body as a ground(it's insulated by the magnet and paint), how can it utilize the car body as a ground plane? Thx.

1. No. SWR will degrade the signal strength. A tuned or resonant antenna will delever the highest signal level to the coax. Impedance (match or mismatch) will affect the transfer of that signal from the antenna to the coax. The closer they match the better the signal will transfer and less loss there will be.
(hey ... this would be a great spot for a RF amplifier ... hint .. hint .. wink .. wink)

2. You have a ground connection thru the coax shield and power cable. Also there is some capacitive coupling due to the size of the base and closeness of the metal body. Works like a "thru the glass" mounted antenna.

The body, hmm... I wonder what ever happened to poor old... what's his
name.

My wife told me to get rid of both of the bodies, she didn't want them
around her kitchen, and so...

I put one up there by where the creek flows under Kildaire Farms Road, the
other I just threw in the lake.

That OK?

Juan, look into a screwdriver type antenna to use as your remote tuned antenna.
It will cover all bands and work great.

Remember this ..... when it comes to a mobile antenna anything shorter than 1/4 wave in length is a compromise in performance. The shorter the antenna the worse it gets.

Richard:

Frederick E. Terman, what a guy.

Every time I am at Stanford I go over and worship at the Frederick E. Terman Engineering Building.

Now there was an Engineer, and unlike the IEEE, of which he was never a member, he was not "reckless" with words. He was an IRE member though.

Richard I am ashamed of you trying to make the allusion that Terman has legitimized "dissipationless resistance" as an actual "thing"!

What?

You are really stretching things by quoting Terman out of context, and even then the qoute you have produced is not definitive. I have his 3rd Edition dated 1947 here by my side, and I too note that he does say, and I quote his words directly...

"for all practical purposes be considered a resistance".

NOTE he did not say it WAS a resistor or resistance, just that it [surge resistance] could be CONSIDERED a resistance for practical purposes.

Considered to be something is not the same as being something.

[snip]
> heat, you can surely catagorize resistances into resistors and into
> non-dissipative resistances. That is what the IEEE wisely did.

SWR does matter for reception. That is why most quality receivers have "preselectors". These attempt to "tune" the antenna. If you "have" 50 ohm impedance, you have a match. The problem is that this occurs at one frequency or specific harmonics

Your mag mount may not be directly connected to the car body, but the negative power lead to the battery is, in turn the shield of the coax is, and there is the capacitive coupling through the mag mount to the body.

The negative lead to the battery is tied by a large braid to the chassis of the vehicle. In essence the entire chassis IS a reference ground.

Richard:

Is resistance not the defining attribute of a resistor?

How many angels can sit on the head of a pin?

Richard by now you have got us wandering way off the topic of this thread.

I don't really care what ya'll call it for it is a non sequitor.

Reg started this thread with some tutorial material on the design of
sources.

I only tried to get those who are misusing the maximum power transfer
theorem, by applying it backwards, to cease and desist.

It is simply not a source designer's theorem, rather it is a load designer's
theorem.

It's simply a waste of perfectly good theorems when they are inappropriately
applied.

Regardless of the existence of "dissipationless resistance,", I care not
whether it exists, the unique optimum source impedance required to deliver
the maximum possible electircal power into a purely resistive load is zero.

All other source impedances pale in comparison!

This is Lewallen's Theorem. Deal with it!

Enjoy...

Heh, heh.

With a 24 foot vertical radiator, I don't think he's mobile. :-)
With radials five meters off the ground, I would use more than three.

Depends on what you mean by "matter". SWR reduces the available signal
but it reduces the accompanying noise by the same amount. Most modern
receivers have a wide enough dynamic range that SWR on receive doesn't
much matter.

> 2. My magnetic 2m mobile antenna on my car is not really connected to the

The capacitive coupling impedance to ground is low so it really
is AC connected to the car body through that capacitance.

Is it unfortunate and a terrible mistake that we use the word
"bus" for the transfer path in a computer? Is it unfortunate and
a terrible mistake that we use the word "key" for a pushbutton on
a computer keyboard? Is it unfortunate and a terrible mistake that
we use the words "tree", "limb", and "leaf" to describe
characteristics of a computer data base? I could go on forever but
you get the idea. Like thousands of other English language words,
"resistance" has more than one definition which is context dependent.

Peter, K1PO wrote:
"Then how much power are they dissipating? (L and C in a parallel resonant circuit in series with a light bulb)."

Peter said the parallel resonant circuit turns the bulb off, so I will assume a perfect or lossless LC circuit.

A perfect circuit has infinite Q or zero dissiation. Inductive and capacitive currents are balanced. They are in fact the same current. Once set in motion, no more current is accepted from the source. The bulb is off because zero current flows through the bulb.

Perfect L and C dissipate no energy at any time regardless of how they are connected. Reactance only can store energy.

I want to replace the am-fm antenna in my 95 GMC pickup with a different one. Could someone tell me what the coax running from the antenna to the radio is? (RG-58)? Am I correct in thinking that the coax end going to the radio is a motorola plug? I like to listen to talk radio on the am band. The fm band works perfectly. I am replacing this antenna because I have an engine noise problem. This noise increases in pitch as the engine revs up. I have tried grounding the antenna, coax, connections, hood, and radio every way that it can be grounded. I bought an expensive silver conductivity paste to ensure a good connection. I have cleaned every connection thoroughly with a small stainless steel brush all to no avail. I installed an inline power filter and as a last resort, I installed a new radio, thinking that the other on must have had a bad filter in it. All that is left is the antenna and coax. This vehicle has factory plugs and wires in it and they are new and in good condition. Does anyone have any recommendations for an antenna and/or coax? Or is there anything else that I am overlooking? Thanks for any advice.

The SWR will have some effect on the reception, The only thing is that you have to measuer it from the antenna back to the receiver. Difficult for most to do as you can't normally put power at the antenna end of the coax and feed it back to the input of a receiver without burning out the receiver. The recievers probably don't have a 50 ohm input over most of the range anyway. Sometimes if a good preamp is used and adjusted for the lowest noise figuer (what you really want) it won't be 50 ohms anyway. Many times with moder receivers they will have so much gain that the mismatch will not be noticed by most hams.

The megnetic antenna base should from a capacitance coupling with the car body. If the base is big enough you get enough coupling the losses in the system are low enough as not to effect things very much. One of the main effects I have noticed is that at highway speeds some magnets don't seem to be strong enough to hold the base in place and the receive signal seem to have a lot of noise in it on a 2 meter FM setup.

By real it is implied that the Current and Voltage are in phase.
Therefore there will be heating.
If there is heating there is resistance. I^2 R it is real enough.
Even if that resistance is only the 377 Ohm / square of free space.
If there is no dissipation there is no propagation. :)

The attenuation is purely inverse square law thinning of the field
intensity.

The coax is some special low capacatiance cable. It is not the same a s
rg-58 or 59 that is about the same size. YOu will have to pull the plug
out to make sure, but the standard for most auto radios is the Motorola
type plug. I doubt that changing the antenna will have any effect on
the reception.

You did not describe the noise problem type. Is it a whine that the
pitch goes up with the motor speed or is it more of a popping noise ?
If it is a whining noise it is probably comming in via the power wiring.
Could be the alternator is getting ready to go out. The popping noise
comes in via the antenna. Try disconnecting the antena and see if the
noise is still there. It might be the hood has become ungrounded or the
other motor and other parts have become unconnected electrically from
each other. Did this noise hapen when the truck was new or did it just
start doing it ?

Gary:

Agreed. Good point.

The free space surge resistance of 377 Ohms does "dissipate" power...

The power expanding outward into the Universe will never return to be reclaimed by the transmitter, at least until after we are all retired.

Richard:

I see that you get reactance, but not dissipationless resistance.

Are not the L and C doing the same thing that your dissipationless resistance does in your analogy of the dissipationless resistance.

You would have a hard time convincing my wife that the L and C in the parallel tank are not acting as a dissipationless resistance to somehow "absorb" the power that was going to be dissipated in the light bulb?

Not much difference that I can see between this and your other example... put the L&C into a black box and do a "load pull" on it, it at various frequencies, by using a variety of light bulbs... see what happens.

1. The impedance seen by the reciever will not be 50 ohm if the SWR is not
1. It will vary along the length of the coax. You will still get a signal
but it will be stronger if you get the swr down. Better still, forget SWR
and tune antenna for best signal.

2, The magnet is one plate, the car body the other , and the paint the
dialectric of a two-plate capacitor. The signal passes through this
capacitor.

Gary Peach wrote:
"By real it implied that the Current and Voltage are in phase. Therefore there will be heating."

The first sentence is true. The second is false.

In the surge resistance of a transmission line the current is in-phase with the voltage when there is no significant loss (heating) in the line. The same is true of radiation resistance in an antenna or the 377 ohms of free-space.

"Inverse square" attenuation of free-space is only a result of spherical trigonometry and has nothing to do with conversion of radio energy to heat.

Propagation is the result of a magnetic wave begetting an electric wave which in turn begets a magnetic wave ad infinitum, as described by J.C. Maxwell.

You seem to think a definite number that is wrong is better than
saying "the result varies". I can't give any exact figures, because
the errors are all over the place. The software simply does not track
the real world, it isn't even remotely close as the frequency is moved
up towards the self-resonant frequency of the inductor.

Have you measured inductors, and compared them to you software? What
is the highest Q you have measured in a reasonably sized inductor at
radio frequencies, and how did it compare to your program's "estimate"
of Q?

[snip]

I love you man, you'r the only one who is paying attention.

You win a free dinner for two at KFC. Because you got Ohm's genealogy
correct.

And... nice going!

Georges Peltier indeed found a way to dissipate without resistance.

In fact Peltier even discovered a way to "un-dissipate".

Peltier's fellow Frenchman, Sadi Carnot probably would have stirred in his
grave if he had found what Peltier had discovered.

Wow, deep stuff, I can see it now, as soon as those "Conjugate Matchers"
read about, but probably won't understand, the Peltier effect, they will
probably "invent" the un-dissipative resistor.

I can see it now... the "Conjugate Matchers" will use a propane heater to
feed heat into their final amplifiers so as to tune the "undissipative
output resistance" until it matches the 50 Ohms of the transmission line.
Instead of "load pulling" they will be "load pushing"!

Now, Gary my buddy, for a free dinner at Wendy's who was Johann Frederich
xxxx?

Best Regards, and thanks again man.

Another approach is to use an open wire folded dipole continuously run between two (preferably plastic) pulleys like the system that used to be used for hanging laundry from high up windows. Feed with 300 ohm twin. The feed point will be in the centre for 160 but by pulling to one side the feed point can be moved (Actually the whole antenna moves through the pulleys) to any off-centre place which gives you a good match at the shack end of the feeder. You will need an ATU there of course - but then you should always have one anyway. ANY band can be worked with this sytem. Total cost about $10. On 18 Mhz for example - dont get a headache working out what current nodes are where - just adjust until you get a match.!
For $2 more you can have a two-sheave pulley at one end with a continuous loop of rope down to the ground to simplify the adjustment procedure without even going upstairs !

If neighbours look askance - just put some wet socks and shorts to dry - loading is unaffected and drying time enhanced by RF.
;-)

Peter, K1PO wrote:
"It is simply not a source designer`s theorem, rather it is a load designer`s theorem."

We have a desire to maximize load power. We have dissimilar source and load resistances. We may find it inconvenient to change either impedance.

Like the 2500-ohm radio output impedance and the 4-ohm loudspeaker we want to use with the radio.

Like the 50-ohm radio transmitter we want to use with a 20-ohm drivepoint antenna.

To get the most power into the loads in the given examples, we reconcile the impedances in each case. We use an impedance matching transformer between the 2500-ohm radio and the 4-ohm speaker. We use a matching network between the 50-ohm transmitter and the 20-ohm antenna.

You can just as accurately say you have conformed the source to the load as saying you have conformed the load to the source.

Peter`s non-conformist attitude doesn`t change the facts. You can accurately go either way with a characterization of the impedance matching process.

Best regards, Richard Harrison, KB5WZI

Hi,

I would like to obtain a copy of the Spring 2000 issue of QRPp. I
am specifically interested in seeing the construction article on
the St. Louis Pocket Vertical antenna. (This is different from the
St. Louis Vertical.)

Can anyone help me obtain this article in one form or another?
I'll do whatever it takes to get a copy of this article.

Backissues of QRPp are available from NorCal only from 1998 back,
nothing yet for '99 or '00. Thanks for your help,

73,

Source record: 170021

Tom said -
> When I measure the Q of an inductor with nearly zero turn-to-turn
> spacing, the Q can easily be half or less what it is when the
turns
> are spaced one wire diameter.
>
==========
Tom, if you take the trouble of using program SOLNOID2 before
criticising it you will find that at HF the computed Q is at a
maximum when the ratio of wire diameter/winding pitch is usually
between
0.5 and 0.7

Also, it is not the increase in capacitance between turns which
reduces Q when the spacing between turns decreases.

3348. What kind of ferrite (RFI)

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-18 20:21:33 UTC
From: PA5KE <pa5ke@euronet.nl>
Message-ID: <96pau9$187i$1@beast.euro.net>
Source record: 170020

Dear OM,

I appreciate some info on the kinds of ferrite that are best usable to fight RFI (common-mode?) in the stereo of my neighbour. The signal is picked up by their speaker cables. I have tried some clamp ferrites on the speaker cables but this did not fix the problem.

What type (ref. number) should I best use, I am active on HF and 6 meters.

Your help is appreciated!

3350. Top of tree within the cone of a discone?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-18 21:05:09 UTC
From: Mark Turner <mark@kram.org>
Message-ID: <jbdp69.7nm.ln@kram.org>
Source record: 170023

I'm considering painting a discone green (non-metallic paint of course) and using a pole to make it sit right on top of a conifer tree with the tip of the tree sticking up inside the cone so that the radials/legs/cone sit almost flush with the tree with very little clearance and possibly even touching the tree in places. The disc will be clear of the top of the tree by some but not many inches. I'll probably leave the vertical element on to help with performance on 6m.

No prizes for guessing that I'm looking for a fairly subtle and low profile installation.

Will the tree being inside the cone have any effect on the discone, for example by altering it's radiation pattern or SWR? My guess is that the proximity of the tree won't do any harm and may even improve the approximation that the discone's legs are making to a cone.

Thanks,

Mark.

Pete Desroche wrote:
"---a good antenna plan (discone) to build?"

The "Radio Handbook" from Editors and Engineers, edited by Bill Orr, W6SAI, 15th edition published in 1959 has a "design chart" for dimensions versus lowest frequency. It goes down to 50 MHz.

I recall seeing a design in which the disk was 6 feet in diameter and the slant height and diameter of the skirt were 9.5 feet. According to Bill orr`s chart the disk is 0.7 times the skirt diameter. That would make the design I saw about right at 27 MHz. The design I saw claimed to cover bands between 11 meters and 2 meters.

Best regards, Ricard Harrison, kB5WZI

Peter:

The kind of trouble you describe will require more than an easy external clamp on ferrite...you can't get enough inductive reactance that way. Most likely, you will need to open up the amplifier and put RF chokes with enough inductance to present a high impedance at the frequencies you are using. Bypass capacitors should also be installed. While you have it open, you should apply the same treatment to the AC power leads if it isn't done already.

This kind of RF filtering, when done on someone else's equipmennt, may cure the RFI problem but it may also subject you to liability for other problems that may occur with the equipmenht, so you should do it only if you are on very good terms with your neighbor.

Rex,
With any 'unbalanced' antenna you are going to have
RF in the shack on some band. You may be just fine on
one or two bands, but there's going to be at least one
band where your going to be 'eaten up' with RF. It's
just the 'nature of the beast'.
I think you won't have 'much' of a ground with just
the one ground rod. You might want to think about using
some sort of feedline out of the basement, then putting
in a radial system. Just a though...

Richard:

All of those instances quoted by you here below, are not really "designs" they are simply adaptations, or bench top fitting together of two different designs. Fitting a previously designed load to a previously designed source. Not really "design", just a "hook up".

However that is, as you so clearly pointed out, a very worthwhile use of impedance matching and the maximum power transfer theorem. I heartily concur with you.

However, if one starts from scratch [R&D perhaps?] rather than just "hooking up stuff" and begins with a green field design for a new source, why then the designer would clearly wish to "optimize" her source impedance, instead of merely matching two existing designs.

What?

Perfection Ah! elusive chalice that knows no decay.

Discussing perfect L and C is a convenient *concept* for understanding
whilst learning, which should not be carried forward into the real world.

i = ((2Ve^(-Rt/2L)/SQRT((4L/C)-R^2))sin((t/2L) SQRT(4L/C)-R^2))

i is the instantaneous current, this expression describes the gradual decay
of a damped oscillation.
The sort of practical damped oscillation (ringing) that you get from the
most perfectly constructed practical LC circuit. Once stimulated into
oscillation that oscillation does not continue forever, it dies out
exponentially unless the lost energy is replaced by an external source.

The expression is the product of three factors.
a constant
a decreasing exponential (called the damping factor)
a Real sinusoidal oscillation.

I think that so far some arguments in this thread have considered the third,
but omitted to mention the first two.

perpetual-motion machine,
a machine, considered impossible to build, that would be able to operate
continuously and supply useful work without needing a continuous supply of
heat or fuel.

A perpetual-motion machine of the first kind, which would produce more
energy in the form of work than is supplied to it in the form of heat,
violates the first law of thermodynamics.

A perpetual-motion machine of the second kind, which would continuously
supply work without a flow of heat from a warmer body to a cooler body,
violates the second law of thermodynamics.

This old lemon has been done to death,
anyone want to discuss entropy?

Cecil:

In a run of "lossless" coax there is no heating! Now if the coax is lossy, of course there will be heating. And depending upon the impedance matching the heating may not be uniform, there may be hot spots along the line located at points of maximim current if there are standing waves present.

If there are no standing waves present on the lossy coax, and the dissipative or lossy line is infinitely long, where is most of the heat generated? Is it uniform all along the line, or what?

BTW... where do you buy your lossy coax?

Heh, heh.

That's why, like you, I use open wires... no "internal" heat loss to speak of.

3360. Need Help Finding / Building Cables for This

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-18 22:12:24 UTC
From: James Wendt <jimw@timeandtech.com>
Message-ID: <cNXj6.5146$Vy2.616639@typhoon.mn.mediaone.net>
Source record: 170032

I need to be able to connect my wireless network access point to an external antenna, but the connectors and cables are giving me fits.
The problem is that the antenna has a female SMA connector and the access point has a reverse male TNC connector and I am not able find anything standard to connect the two.

I can't and don't want to change the connector on the antenna though I have been able to find an adapter which turns it into a standard female TNC.

I could probably change the access point since the guts of the thing are basically a SMC PCMCIA wireless network card attached directly to the board. The built-in PCMCIA card has an industry standard female connector which is connected to the reverse male TNC connector by a short, skinny piece of coax.

I'd appreciate any advice you could share about where I can either buy the adapters (this isn't my first preference due to potential signal loss) or where I can buy the parts to change my access point from reverse TNC to female SMA so that I can use standard coax to hook this all up.

(See pictures of what I'm working with here: TNC / SMA connector problems http://www.manlycooking.com)

Please contact me at: jimw@timeandtech.com with any suggestions.

Thanks in advance,

Jim Wendt

Get two ferrite cores of type 43 material (or other material with
initial permeability about 850 or greater). Wind several turns of each
speaker cable (both conductors together) through a core. 5 turns will
give as much impedance as 25 clamp on cores of the same size, 10 turns
as much as 100 cores. Put these as close to the stereo as possible. The
larger the core cross section, the more impedance you'll get.

Seems to me that I saw an article suggesting that you put a small container of your prospective paint into cup and into the microwave. If it gets hot when you blast it, don't use it. Or, brush some of it onto some material which you've already proved to be OK in the microwave and give it a shot that way. Any heat... don't use it!

> wink .. wink)

More devastating the VSWR if bad would actually add to the noise.
Now this would hardly be noticed at HF (below 15 MHz) but at higher
frequencies where the sky temperature begins to approach Receiver
temperature (noise figure) A bad VSWR can wipe small signals right out.

> 2. You have a ground connection thru the coax shield and power cable. Also
> there is some capacitive coupling due to the size of the base and

Um!
Imagine a mag mount in the centre of the roof of your car.
Now for a moment let us consider static electricity, (you know the sort that
you get when you comb your hair in dry weather)
Imagine if you will that the tip of the antenna has a collection of
electrons on it thus a large negative charge. Now get out your electroscope
(Pith balls or bits of cellophane or very dry bits of fag paper) They would
line up along what the original experimenters called lines of electrostatic
influence.
Bit harder to do than the equivalent magnetic demonstration where you
simply put the magnet into a load of iron filings and they line up along the
lines of magnetic influence.
What you would see is a concentration of lines of electrostatic force
bunched together around the tip of the whip and they would be spread out
like a fountain with the other ends of the lines of influence terminating in
the first positively charged body. namely the roof of the car.

Now if you will come with me a bit further and consider that instead of an
electrostatic charge at the tip of the whip you substitute an alternating
high voltage, first a surplus of electrons at the tip making it negative and
next the electrons rush away and leave holes thus a positive charge.
The positive charge will have similar lines of influence in the form of a
fountain just the same as for the negative charge, but the field which they
represent will be in the reverse direction. So in space when an oscillating
voltage is applied to the antenna an oscillating electrostatic filed will be
produced in the space around the antenna. as the electrons rush away from

the tip they will constitute a current and a magnetic filed will circle the whip.
Now in space we have an oscillating magnetic field normal to (at right angles to) an oscillating electrostatic field in space. We have in fact an oscillating electromagnetic field radiating away from the whip.

Any nearby conductor will act as a terminator for the electrostatic lines of influence. The same is true if you consider the wave when it has progressed on its journey. It is by this mechanism that you get reflection, that targets are detected by a Radar, that multipath (Ghosts) spoils a TV picture.

> frequency or specific harmonics

Be careful not to confuse a preselector with an antenna tuner.
Both do a little of each others job but each has a specific purpose.
A preselector usually will have a much higher Q than an Antenna tuner.
It will have very much higher rejection of unwanted signals outside the pass
band of operation.

An Antenna tuner is purely an impedance matching device and the Q is low.

If you have the choice for receiving then go for the preselector.
If you are above 15 MHz then go for both.
At VHF you have different methods of accomplishing the desired result.
However Matching of a Receiver Antenna if you want ultimate sensitivity and
low noise (best Signal to Noise Ratio) is important.

The XYL and I are in the process of building a new home on 4 acres and will be moving in this spring. I'm starting to dream about my new farm (antenna, that is). I haven't finalized the design of the antennas yet, but I will probably initially put up the tower and antenna that I'm using here (once I get some extra cash I do want to upgrade, but that may be a while). I'm mainly interested in HF.

I'm looking for advice on feedline. Obviously the more I pay for feedline, the less loss, but what's the best bang for the buck. There will be 150 - 175 feet of feedline from the shack to the top of the tower.

Hmmm... I've heard folks commenting about Station Masters coming apart internally due to flexing in the wind... especially the UHF guys with their many, many soldered joints. Our club has gotten away from them in favor of the multi-bay dipoles... expensive but rugged to the max!

> much matter.

You can't improve upon the S/N at the input to the antenna,
but you can degrade it.

The ideal is to realise as near as possible at the output of the receiver
the signal to noise at the input. Anything that you fail to do that either
degrades signal or increases effective noise will spoil the output signal to
noise

(So/No)/ (Si/Ni) = So/Si * Ni/No

here we have two elements to receiver performance.

The SWR will affect both of these components.
The effective attenuations are available from tables.
Thus signal attenuation is easily calculated
however let us look at the noise

N = kTB
where k is Boltzmann's Constant
T is the absolute temperature
B is the bandwidth.

therefore Ni = k Ti B

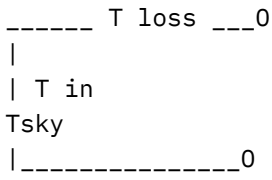
Ti is Temperature in

Noise out = Noise in plus noise generated in the receiver
= Ni + Nr
= k Ti B + k Tr B

Simplifying
= kB(Ti +Tr)

Let us look a little closer at Ti

It has two components,
Tsky and T loss



T loss = To (1- loss)

Tin = T sky * loss + To(1-loss)

Now the loss consists of two parts the actual insertion loss due to the feeders etc. and the effective loss due to a miss match.

Where T sky is very large as at the low end of the HF spectrum T loss is not significant. However as the frequency rises the sky noise falls off at 8 dB per octave until the sky noise begins to approach the noise figure (Tr) of the receiver, now these effects begin to become important. The effects starts to take effect above 15 MHz being quite small at that point and gradually becoming more significant as frequency increases.

So/Si * (Ni/(Ni + Nr)) = So/Si* Ni/(1+Nr)
Nr is affected by feeder loss and Feeder VSWR.

If you are a moon bouncer or a meteor scatterer, or a troposcatterer then you will pay special attention to low feeder loss and good VSWR for a receiving Antenna.
If you take a pride in your art you will always be jealous of these factors as major contributors to your stations efficiency.
Why spend several thousand on a good receiver and then spoil everything at the point where attention to detail has the greatest return smacks of sloppiness to me. And dare I say stupidity. :)

It's pretty simple, e.g. sin(30deg)=0.5 arcsin(0.5)=30deg
The arcsin of a number is the angle whose sin is the number.

If you're in a real pinch, one of the better C.B. meters, the ones which use the parallel line construction will work surprisingly well on two (maybe even on 440, although I've not tried it yet). To make sure that it's working correctly, hook it up normally, take your reading and then reverse it and call Forward reverse and vice versa. If you get the same readings both ways, it'll be usable to detect a null (1:1)... but, the actual SWR values will be off.
Probably a used Bird 43 and a couple of slugs would be a good way to go.

DON'T DO THAT!!

Most paints contain volatile solvents - at least, the ones you would use
to paint antennas do. Filling a microwave oven with flammable and/or
toxic vapor looks like a great short-cut to a Darwin Award!

The properties of the paint change considerably when it's dried, and
unless it is grossly lossy you will never notice the temperature change
in a thin film of paint.

The microwave oven test has its uses, but this isn't one of them!

Wet ground is better than dry ground. Put some sprinklers in and plant
grass. The ground will be better and it will look better.

Only use salt if you don't want Carthage to rise again.

See if Fair Radio still has some of the Struthers Watt Meters. They may be listed as
a URM-120. It will go from about 80 meters to 1000 MHZ and a full scale of 10 watts or as much as 500 watts from 30 to 1000 mhz. This is by changing slugs smilar to the Bird 43 wattmeter. You should be able to find them from abut $ 120 to $ 150. Make sure you get the three slugs that normaly come with it to cover this range.

While this may seem high, it will cover most needs for swr from the low bands to uhf.
There are very few other meters that can do this.

Actually Ford does have a TSP on the subject, but it applies to their Tempo line. It involves dropping the tank, uninstalling the pump/fuel gauge assembly, cutting the leads to the pump and installing a bifilar wound choke between the pump and the tank feedthrough connectors.
The same technique *might* work if it was just installed between the vehicle harness and the tank connectors, but the tank was metal on those models... the shielding probably helped some.

I might add if someone does do a microwave test for some reason or another, always put a glass of water in the box along with the item to be tested. I hear it's bad to run a microwave empty. If the item to be tested is indeed non conductive, you want the glass of water in there so it won't be running "empty". MK

As you know , the input impedance of the load must match the output
impedance
of the source for 100% of the power to be transferred.
A high SWR affects reception as well as transmission, SWR is usually lowest
at the resonant frequency the antenna is tuned for.
Magnet mount antennas use capacitive and inductive coupling similar to a
thru-glass mount.
Neither of these antennas are very efficient for power transfer.
Top-loaded antennas see more of the signal before being attenuated by the
loading coil, this is why i dont like base-loaded antennas which attenuate
the
entire signal before sending it to the radio.

3384. Re: Random Length Wire Antenna Question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-19 02:04:25 UTC
From: "Stan Labinsky Jr." <stanbarb@warwick.net>
Message-ID: <3A907F29.2D9D6410@warwick.net>
Source record: 170060

A few things...
1) The length of the wire from the tuner to ground WILL be resonant at some of the higher frequencies. You do NOT want it to be a quarter wave length (or any odd multiples of a quarter wave, 1/4, 3/4, 5/4, etc.) on the bands of interest or it'll look like an open circuit... like it's not there to the RF. That would be about eight feet on ten meters, for instance.
2) Be wary that you do not have high levels of RF voltage at the tuner... no half wave lengths of antenna and feed line (taken as a total length) at any of the bands you plan to use.
3) The ladder line feed will not be balanced and therefore will not cancel out the fields around it... the feed line will radiate. Still may be better than just a single wire, though.
3) Lightning protection will be a problem. Go for the best ground you can make, right from the cabinet of the tuner. One inch copper strap (minimum) instead of wire... it's less inductive, more capacitve... less impedance to the strike current. Also, NO sharp bends... they increase inductance! One ground rod is not sufficient! Two would be better and they should be spaced twice their rod lengths apart (one close to the building, the next one out away from the house). Any closer and they will begin cancel each other out (the earth around the rods does saturate electrically during a strike). Also note, it's not the resistance which determines how poor a lightning ground is, inductance is the culprit! The energy contained in a lightning strike is spread out over many frequencies (DC to light on a decreasing scale)... the higher the frequency, the higher the voltage... E=I x XL, XL= 2Pi x L x F <= frequency, that is. Don't believe it? Listen to the racket on 80 meters during a thunder storm. In a real good one the noise'll extend up to two meters.
Tie the radio and any other box that is connected to the radio to that ground. The last thing that you want is to have the strike looking for ground at the service entrance panel (breaker box)... chasing up the safety ground lead (the third wire in the line cord) and through the house wiring to get there.
As far as removing the energy from the feed line, most strike abatement equipment is designed for coaxial feeds, with the shield firmly grounded at many points. Surge suppressers are designed to shunt as much energy from the center conductor to the shield as possible. With a single wire, given that there may be high voltages on your feed line just because of standing waves, a surge suppresser might fire the first time you say, "hello"... protecting your antenna from your signal... and making your rig very upset. An old fashioned spark gap might be a workable choice, the ARRL Handbook might give you some help there... an older one probably. And yes, the gap must be tied to your ground rod network which should be as close to the feed line's entrance into your dwelling as practicable. Which brings up another point:
The antenna feed line(s) should come into the house where the electricity and the phone lines do (their respective grounds should all be bonded together there). The idea is to have all the wiring in the house "jump" with the strike

so that there are no differentials from one end of the house to the other. The same applies to the equipment, that's why it all gets bonded together, so the interconnecting cabling doesn't have to carry the bulk of the strike current. Now, does that G5RV with buried coax begin to look a little bit better? ;)
If you want the gory details of lightning protection, look up Polyphaser's web site and order their "Grounds for Lightning Protection". While the book pushes their products, the supporting material is hard to ignore.
Hope this's helped, Rex... 73!

When the spark plug wires go bad the insulation breaks down and can cause
the whining sound you hear.
A faulty diode in the full-wave bridge rectifier of your charging system
will
mix a little AC ripple in with the DC and cause audible whining that
increases with RPM.
Start with the cheapest solution, goto R/S and p/u a inline noise filter for
the
power cables going to the radio.
Changing the antenna is not the solution.

Many Stationmasters were designed for typical 5-MHz commercial repeater splits, and may be abnormally noisy when used for ham repeaters with 600-kHz seperation (2-Mtrs). At one time, the manufacturer strongly suggested advising if the antennas were going to be used in ham repeater applications (this goes back at least 25 years or so...)

I was involved in maintaining a local repeater system for almost 30 years, and I have become more and more in favor of the exposed dipole arrays over the fiberglass colinears. Quality doesn't seem to be as good as it once was, we had a few sticks develop noise after a few years of mountain top use. Our oldest four bay exposed dipole array (Sinclair, 25 years old) is still going strong.

Mark,
If you plan to use coax, and will be mainly on the HF bands,
RG-213, or the equivalent, will work as good as any. I wouldn't
worry about losses too much, not on HF.
'Doc

If the noise has a musical whistling sound, it's more likely coming from the alternator. An... oh about a half microfarad feedthrough capacitor suitable for the current capacity of the alternator might help. Mount it right on the alternator's case, run a jumper from the alternator's "Batt" terminal to one end of the capacitor, connect the lead that went to the "Batt" terminal to the other end.
If the noise is very raspy and you can almost count the pulses at idle, try cleaning the ignition cap, rotor and wires... after documenting where each wire runs from and to ('been burned by a bad memory on that one).
I use a hot strong dishwash detergent and water mix (should feel a little greasy) followed by a hot rinse with a baking time in the oven. 250deg. for a half an hour usually comes out a delicious golden brown... and very dry too!
This also works for the engine which just won't fire in very damp weather or one which likes to stall out running in a heavy rain storm, like my Plymouth van (V6) used to do. Oh, before you wash the wires, check their resistance... somewhere between 5k and 10k should be about right... often the longer ones will measure higher, but 20k plus is a bit too high. Flexing the wire while measuring it should show no change... as long as you are making good contact with the meter's leads.
You might want to make sure that the plugs are "resistor type". If you're not the original owner they may have been switched on you by someone thinking that he'd get better performance by doing so. With an old points and condenser ignition... maybe, but not with the electronic types so common today.
Also, make sure that the antenna's mount is well bonded to the vehicle's fender and that the fended is bonded to the truck's chassis... six years of use can loosen stuff up and allow rust to set in which'll ruin the original bonding. Things do rust in Alabama... don't they? ;-)
Many years ago the coax used to be high impedance, air dielectric with a very fine center conductor... used with a long antenna. With the advent of F.M. and quarter wave whips, the cable is more like 50 or so Ohms. The AM performance suffers because a 30" whip is such a poor antenna at 1 mHz. and low impedance cable adds soo much capacitance to ground that it becomes troublesome to match the antenna system to the radio's input.
If you can find an older style pull-up antenna, try it... you'll just have to collapse it when you want to listen to distant FM stations. Might find one at a truck stop electronics counter. And yes, that funny plug on the end is a Motorola.
Oh, another possible source of AM noise is the electric fuel pump... if you have one. They can be nasty to deal with. But their pitch is usually pretty constant and is there for about a second or two after you've turned on the key but before you turn the engine over.
Good hunting... Stan

All you need is a DC path and return. Why can't you use DPDT
relays for that? Each relay will enable the next relay.

I've never tried that, but judging from using other antennas near metal houses, I doubt it would do very well. I'd try to get away from the house with loops or other wire antennas. One of those things you just have to try to see I guess. MK

I had an A3S here and liked it. Mine had the 40m add-on, and did
well on 40 meters. My suggestion- look for a used Force 12 C-3 or
C-3S. You would probably get better long term reliability out of one
in that windy environment. There are just an awful lot of connections
in a trap tribander that can open up. I had a 10 meter DE trap open
up in mine. The aluminum wire in the trap had cold-flowed and worked
loose under a stainless steel screw head. It was an older antenna,
however. 73, David K3KY
P.S. I have a C4XL and I like it.

Where if comes into contact with mass it does heat it up.
You stick a receiving AE into the path and the I/P resistance of you set
will heat up.
You'll have a problem measuring it though.

Here's another old chestnut for you.
#A high Power TV transmitter fills a service area.
Can you keep adding Receiving sets indefinitely?

The key word is "Significant", You are arguing the degree of heating not if it occurs or not. This boils down, (pun intended), to the quality of the materials used for the construction of the line.

>The same is true of radiation resistance in an antenna or the 377
> ohms of free-space.

Believe me when the Electromagnatic Wave reaching out into space eventually encounters some mass ther will be heating. Be it ever so small never the less ther will be heating. If this is not true then a microwatt of power can communicate over any distance to as many places as you wish. We all know that to be false, and some spend enormous sums of money on Linear Amplifiers to overcome this natural affect to some degree.

Did I say otherwise?

> Propagation is the result of a magnetic wave begetting an electric wave
> which in turn begets a magnetic wave ad infinitum, as described by J.C.
> Maxwell.

True untill it encounters Mass, when the energy exchange between the fields is stopped by the heating of the mass.

3403. HF signal levels in town vs out of town

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-19 12:50:55 UTC
From: jeraa2t@nospam.ultranet.com
Message-ID: <3a9115dc.560970@mdnews.btv.ibm.com>
Source record: 169977

I noticed while mobile this weekend on 20M, that the signal levels in and around town are much lower than out over the open highway. I have noticed also near the ocean signal levels are better even the upper bands on HF. Has anyone look at the shielding effect of all the overhear wiring that typically runs around town ala. cable, power, telephone etc..
I know that there are some vhf/uhf models around but nothing on HF. And how high above that cabling you would have to be in order for it to not effect things if you had a beam on a tower ?

Just a thought. AA2T

I didn't see the original post, so I may be answering the wrong question. However, if the tree is inside the cone portion of the antenna, I wouldn't think it sould have much of any impact at all. Wouldn't the fields within the interior volume of the cone cancell and the RF energy tend to stay on the outside surface?

MFJ made and sold as the MFJ259 what I called the MFJ 259A. It was/is a model in-between the original 259 and the 259B. Physically it looks just like the "B" model and has some of the features of the "B" but not all. of them. I asked when the "B" model came out, if it could be upgraded to the "B" as it looked like it just needed a software upgrade. I was told by MFJ I should be happy with what I had and it couldn't be upgraded. The box works well and if the "B" model had not come out days after I bought mine I would have been happier but the tone of the answer I got from MFJ was not appreciated. I don't mind that it couldn't be upgraded, that's their call, but I didn't need to be told I should be happy with what I had. Anyway the radio shack sold VEC 584B sounds to me very much like the "A" model I have.

Something along those lines is what I'm hoping. I figure that the inside of
the cone is similar to below the groundplane of any other aerial.

Cheers,

Mark.

Gary Peach wrote:
"The key word is signficant."
I had written: "In the surge resistance of a transmission line the current is in-phase with the voltage when there is no significant loss (heating) in the line."

Well, had I omitted "significant", some would react with "There are no lossless lines". There are plenty of lines that might just as well be lossless.

I am also amazed at how many who should know better think the characteristic resistance of a transmission line is a loser.

Gary also wrote:
"Be it ever so small (mass heating of antennas and things extracting energy from a traveling r-f wave) never the less there will be heating."

Antennas have currents induced by a wave sweeping past. Especially when they are well placed and near to being a resonant length. If they are matched to a load they may extract up to half the power from a small area of the passing wavefront. The other half will be re-radiated. Receiving resistance produces heat.

The reason a microwatt can`t radiate into space and communicate indefinitely has nothing to do with sinks soaking up all the energy in the wave.

Every receiver has a sensitivity threshold. When a wave expands to a thinness in microwatts per square meter that is too weak to operate the receiver, it no longer provides satisfactory reception.

If we could concentrate radio energy into a column that would not spread out, we could aim it at any unobstructed point in space and communicate using extremely small power. It`s the spreading of the wave that`s our downfall, not absorption.

You can. Problem is all the surplus vacuum relays I've seen are SPST
or SPDT.

It isn't a very practical idea, unless you run very low power and
don't mind working on the antenna on occasion.

Propagation of EM waves in "free space" is not the same as dissipation of EM energy in the form of "heat".

Assume a perfect isotropic radiator. Field density (or intensity) decreases with distance away from the radiator because the total radiated energy is distributed evenly over a sphere of increasing radius. This reduction in field density is not really an attenuation or "loss" of energy. At any distance, the total energy distributed over the sphere remains unchanged. We define this phenomenon as "path loss" only so that we can describe the decrease in the field density in terms of distance and wavelength.

It's a well documented fact that on low bands, ground conductivity places a terribly important factor on signal levels. Chewing up the ground for construction, roads, et. al. in a city or any other environment lowers the ground conductivity, per the references I've read. Undsiturbed soil in and around creek bottoms, marshes, especially a salt marsh, make for better signals on HF, particularly low band work.

I'll relay, again an experiment I played with a VK3 on 40 CW. I've posted it here before, but it's a fun story.

He had a sharply tuned loop antenna on his car! Said it attracted lots of attention from the curioys, but it worked very well. He an I used to talk frequently on 40CW at our sunrise when he was going home from work. His home was inland a bit, but close to the ocean coast line for the Pacific, and the road there wund out from Melbourne to that coastal road, then past a cliff with a public boat ramp under it. The cliff overloos the ocean.

On the way home from work on the road, one segment of it had concrete and re-bar in it; another segment did not. He would often have to stop and retune the loop going from the one to the other! Did it at traffic lights, if I recall! He'd jump out and tweak it a red light I think! You could see an actual difference between the re-bar road and the asphalt run!

As he drove along the coast line, he would be maybe S3 or so until he would get to the bluff area where the road began to run along the blufff overlooking the ocean. At that point his signal would rise two or three S units! Then, he would go down the road to the public boat ramp. As he approached the ocean, his signal would rise some more. He'd drive the car down into the salt water, optimum tune the loop, and his signal

would be up at S9 on the meter, ofen more. As he backed out of the water and moved back up the road to the bluff, his signal would go back to what it was before he left it.

Fron there he had to turn down a side road to go home. As he drove the mile or two back to his home site, his signal would fade down to S3, often into the noise. We could communicate while he was in his driveway, barely, at times. Of course he could go in and fire up the fixed rig and do OK.

Now that's from S3 to S9 plus at times, just on the basis of aperature effect and ground conductivity near salt water. And, no, I didn't, don't have a calibrated microvolt-aware black helicopter receiver to give you the precise signal levels. And no, because of the timing, there really wasn't much effect of path decay from the sunrise at my end which would have accounted for much of this.

We repeated this experiment a number of times. The results were the same. In fact, somehere in my audio tapes, I have a tape recorded session of it, buried deep in the box with the ones where I figured out how to kill the woodpecker and get it out of 40 meters in the early morning, plus the actual ID for the "V" beacon, which is/was RCQ45. "V" is gone now, too, chuckle! But "P", "S" are still there chirping away on 7038.8 and 7038.9, maybe "C" and "K" too, up there!

The effects of ground are less, I've seen on 40 than 80. Obviously, as a low band fanatic, I'd be interested. Although I do not work 160, the same is true there, with a side-bar comment. From what I have read, there may be a somewhat different propagation scenario on 160 as you go down toward the broadcast band, which changes the picture a little. W8JI can tell us that here I suspect.

I don't work 20 and up. But I suspect that the effects of ground conductivity decrease as the frequency goes up. Some of it, obviously, has to be present there on 20.

Here where I live in Suth Central Texas, I'm a few DB better off than just about 20 miles to the fault line that starts all the sand country and pine trees of the Conroe, Livingston, Beaumont area in Texas. You get into sand country and things get worse, but they are still bad here, compared to the coastal plain in Texas, and worse than the black gumbo up near Waco and in areas around Dallas which are pretty good.

Over forty years of this, and travelling around, comparing notes, my QTH is down about 3 DB or so from these other better sites on low bands, here in Texas. The overall path from either coast to me, is down at least 10 DB, and I suspect maybe more, on average, from what the East Coast folks see for Europe on low band, and the same is true for the West Coast on Asian paths.

What you've seen is a beautiful example of why those with money that are really concerned about ham radio .. move to places where it is easier to win. It still the real-estate game, location, location, location. And

when you get down to that, add some more location.. chuckle!

The effect is well documented, especially when in the game you compete
with someone who has the keys to the kingdom right there on the ground!

--> Sleep well; OS2's still awake! ;)

3412. Re: What kind of ferrite (RFI)

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-19 15:17:09 UTC
From: Larry Benko <benko@aztek-eng.com>
Message-ID: <3A9138F5.CCD31575@aztek-eng.com>
Source record: 169987

Peter,

Roy is correct that a larger ferrite with more turns is better than several single turn ferrites. I had an occasion to make some measurements on some Amidon FT240-43 and Steward 28B material toroids of the same size (2.4"OD x 1.4"ID x .5"H). Both these toroids were u=850 types. The wire I wound on the ferrite was #14 THHN type and the winding was a single layer fairly tight over x% of the toroid. The dB. attenuation values were referenced to a 50 ohm system.

```
------------ Attenuation ------------------
Number Turns 3.5MHz 7MHz 14MHz 30MHz 50MHz 100MHz
4t (25%) 9dB 13dB 17dB 20dB 21dB 22dB
6t (33%) 15dB 19dB 23dB 26dB 28dB 29dB
8t (40%) 20dB 24dB 28dB 31dB 32dB 35dB
10t (50%) 24dB 28dB 32dB 35dB 37dB 42dB
12t (60%) 26dB 31dB 35dB 38dB 40dB 30dB
16t (70%) 31dB 36dB 41dB 43dB 43dB 20dB

1t (clamp on 1dB 3dB 5dB 7dB 9dB 11dB
ferrite 5/16"ID)
1t (clamp on 0dB 2dB 3dB 5dB 8dB 11dB
ferrite 1/2" ID)
2t (clamp on 2dB 5dB 8dB 13dB 16dB 20dB
ferrite 1/2" ID)
3t (clamp on 4dB 8dB 13dB 19dB 23dB 28dB
ferrite 1/2" ID)
```

The attenuation in dB can be converted to impedance but 10dB~=216ohms, 20dB~=900ohms, 30dB~=3060ohms, 40dB~=9900ohms.

Ferrites do their best when the source impedance of the offending signal is low and when the load impedance for the offending signal is low. A second nearby series ferrite will double the voltage loss (6dB) but a second ferrite several feet down the cable may improve things much more (or not at all) due to the impedances. The clamp on ferrites don't do much on HF. The big ferrites cost ~$6US new from Steward or ~$9 from Amidon and can sometimes be found surplus but then you need to measure the ferrite material. Is should also worth mentioning that jumble winding the turns or using more than 75% of the toroid decreases the effectiveness.

73,
Larry Benko, W0QE

The total "receiving resistance" is comprised of radiation resistance and
loss resistance. It is the loss resistance component that converts received
energy into heat.

I have been considering the MA5B myself. I live near the
Cushcraft headquarters, and have the opportunity to drive by
the facility on occasion. I got a glimpse of the MA5B several
months before it was released at Dayton. They have one on their
tower that is probably in an ongoing test.

Last week I noticed that the elements are no longer in the same
plane. It looks as if an element to boom clamp has broken. So I'm
going to be a bit more cautious before I purchase one of those.

I will say that they probably do a lot of assembly and disassembly
with this particular antenna. So it may be more subject to fatigue
failures. On the other hand, maybe they have found a way to
squeak out another .5 DB.

Peter, K1PO wrote:
"Fitting a previously designed load to a previously designed source. Not really "design", just a hook-up."

I`ll answer. First, I apologize for earlier saying energy dissipated is volts times amps. That is of course power. I avoided the word power because some people hate the word. Energy is volts times amps times time, of course.

Now, in the examples we had a radio receiver, a loudspeaker, a radio transmitter, and a transmitting antenna.

The radio receiver output impedance is a function of practical voltage and current the output device(s) will withstand, or the design can supply.

The speaker`s electrical impedance is determined by acoustic implications of voice-coil mass.

The transmitting antenna`s impedance is determined by choices made to get certain radiation characteristics which are the "job-one" of the antenna.

The transmitter`s output impedance is determined by the line impedance likely to be used with the transmitter. This is because the transmission line is usually long enough in terms of wavelength to permit voltage and impedance variations within its length. Characteristic impedance is then important. So, it makes more sense to accomodate a transmission line impedance than the final load impedance.

There are good reasons not to bother about a new design effort to make the sources and final loads equal to each other rather than adapting the usual dissimilar impedances.

Best regards, Richard Harrison, KB5WZI

3416. Re: Relays instead of traps in a beam antenna???

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-19 16:24:50 UTC
From: Richard Karlquist <rick@area.com>
Message-ID: <mNbk6.10309$5M5.664616@news1.frmt1.sfba.home.com>
Source record: 169990

I have a 90 foot vertical (three 30 foot irrigation tubes) for 160 meters.
It has relays at the 30 and 60 foot levels to make it a 1/4 wave
on 80 or 40 meter. I had considered using pneumatic actuation, but ended up
with latching vacuum
relays. At the 30 foot point, there is a pF or two of gap capacitance plus
another pF or two of
relay capacitance. I resonate this out with an inductor wound on a 4 inch
ferrite rod. The ends of
the inductor have blocking capacitors at the ends. This inductor allows me
to get a DC
connection across the gap. The wiring is as follows:

Wire #1 runs from the base along the vertical tubing to the 30 foot relay
coil.
Wire #2 parallels wire #1 up to the 30 foot point. There it is bypassed
with a capacitor
to the top of the lowest tubing section. It also connects to the bottom of
the inductor.
The top of the inductor is bypassed with a capacitor to the bottom of the
middle tubing section.
Wire #3 connects to the top of the inductor and runs alongside the tubing up
to the 60 foot relay
coil. The return for the relay coils is thru the tubing.

I have to have the 30 foot relay closed in order to be able to switch the 60
foot relay.
So I can't switch directly from 160 meter to 40 meters. I have to go
through the 80 meter setup first.

The relays are pulsed with current from a charged up capacitor. I remote
the capacitor
out at the antenna which is 1000 feet from the shack. This is analogous to
remoting the
motor capacitor on a rotator. There are steering diodes at the relays so
one polarity opens
the relay and another closes it.

It would even be possible to mount the capacitor for the 60 foot relay right
at the relay,
(along with a control circuit) and then replace the inductor at the 30 foot
level with a large
(megohms) resistor. Power would be continuously applied through this
resistor to keep the
capacitor charged. A pulse could be superimposed on this DC bias to signal
the control circuit

to switch the 60 foot relay.

I didn't do this because I consider the inductor across the 30 foot gap to be an advantage because it
decreases the coupling to the middle tubing when on 40 meters. I am building a phased array and
I don't want parasitic currents induced in unused tubing sections.

I will have to admit I have had some reliability problems with the 60 foot relay. I am still trying
to determine what is going on there, perhaps condensation. I may have to pot the assembly. The
30 foot relay has never had any problems.

I was just thinking about a relay Yagi yesterday. It would have 33 foot elements with loading
coils 2/3 of the way out to make it work on 30 meters. For 20 meters, relays would short out
the loading coils and I would have full size elements. For 17 meters, the relays would open up
and remove the coils and the outer 1/3 of the elements. I don't think you could do this with traps very easily.
Just brainstorming at this time.

3417. which coax for 2 Meter?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-19 16:25:23 UTC
From: davekle@city-net.com
Message-ID: <3a914828.84558454@news.city-net.com>
Source record: 169979

I'm getting ready to elevate my 3/4" copper pipe J-Pole antenna and I'm trying to figure out which type of coax to use. It obviously needs to be weatherproof but I don't want to spend a fortune. I'm probably going to need about a 80-100' run.

Any suggestions on where to buy coax online?

Any suggestions/opinions would be greatly appreciated.

Thanks in advance.

Hello, Can someone tell me how to determine the velocity factor of co-ax? At present I am using RG-58. I am making a co-ax matching, shorted stub tuner. Is there smaller diameter 50 ohm cable that will carry 100 W, (I have a space problem)?

Very Best Regards, Arthur KC6KUK

Steve, VE9SRB wrote:
"The total "receiving resistance" is conprised of radiation resistance and loss resistance. It is the loss resistance compnent that converts the energy to heat."

Agreed. I was thinking of further sub-division. The whole system includes the receiver`s input resistance.

The radiation resistance becomes the "generator resistance" for the system. Line loss turns some of the received energy into heat. Then, some of the energy is absorbed by the receiver input which is the load for the system.

Energy lost in the radiation resistance is, of course, that which is re-radiated by the antenna.

Best regards, Richard Harrison, KB5WZI

From the widely available manufacturer specs in catalogs, handbooks, websites, technical books in your local library, etc. Typically, solid polyethylene insulation results in the VF of 66%.

> At present I am using RG-58.

VF = 66%, unless the dielectric is *foamed* polyethylene.

> I am making a co-ax matching,
> shorted stub tuner. Is there smaller diameter 50 ohm cable that will
> carry 100 W, (I have a space problem)?

You don't say what frequencies. In SW, RG-174 (VF = 66%) or RG-316 (VF = 69.5%) should be able to handle it, at the price of increased attenuation.

Seems, since the DC current is relatively low, one could also install
an inexpensive RF choke at each junction.

Source record: 170001

I've had lousy luck with clamp on cores (RadioShaft). I'd like to try the cores mentioned below at the best price I can find, Suggestions please.

When the percentagtes are mentioned below, are we talking about close winding the wire so that say, 2/3 of the core has nothing on it.(33%) ..or spacing the wires to cover 100% of the core, but with significant spacing between each turn, so that only 33% of the total core has wire covering it, but the wire/coax etc, is wound around 100% of the available area of the corp (360 degrees).

That wording is terrible...do you use the full 360 degrees of the core, or only say 270 degrees, to keep to the 75% mentioned below. Using 360 degrees, the wires would be widely spaced, but evenly distribututed across the 360 degrees of the core. Using 270 degrees, the wires would be closely spaced, and 90 degrees of the core would have no wires on it at all. Which is appropriate?

Source record: 170007

There is one more way of determining the sign of the impedance angle from the magnitude of Z and SWR. It involves varying the test frequency through an impedance resonance - if there is one.

It is a fundamental property of resonant circuits, including resonant transmission lines and antennas, that -

(1) As the magnitude of Z passes through a minimum in the Z/F curve with increasing frequency, the reactance of jX is negative on the low frequency side of resonance, jX is zero when exactly at resonant, and jX is positive on the high frequency side of resonance.

(2) As the magnitude of Z passes through a maximum with increasing frequency, jX is positive on the the low frequency side of resonance and negative on the high frequency side.

That (1) is true is demonstrated by considering the input impedance of a simple series L and C circuit, or a 1/4-wavelength of transmission line open-circuit at its other end.

That (2) is true is demonstrated by considering the impedance of a simple parallel L and C circuit, or a 1/4-wavelength of transmission line short-circuit at its other end.

At HF it is also a fair bet that as SWR varies with frequency, at a minimum SWR the line + antenna is resonant and jX is zero regardless of the value of R or the minimum SWR. But the accuracy of the usual SWR meter must be taken as a warning - don't bet your life on it !.

Source record: 170002

More important might be current crowding due to proximity effect. Every Q prediction program I've seen (admittedly not including Reg's) predicts higher Q -- often much higher -- than I can measure. I've felt this was most likely due to failure to account for proximity effect, but I've never known for sure. We did have some discussion on either this or the homebrew newsgroup a while back about the real meaning of inductor Q and whether it should or shouldn't include the effect of shunt capacitance. Some methods of measuring Q include the effect of shunt C (that is, the Xl becomes modified by the effect of shunt C) and some don't. The consensus was that you really need to specify whether shunt C is included or excluded when you specify inductor Q, and you need to be aware of what your measurement includes.

RG-174 (0.1 inch outside diameter) easily handles 100 watts with a moderate SWR. Your application, though, sounds like it might involve lines with high SWR.

Date: 2001-02-19 20:57:00 UTC
From: Larry Benko <benko@aztek-eng.com>
Message-ID: <3A91889C.AB9820EA@aztek-eng.com>
Source record: 170009

Hasan,

Generally use a single layer winding occupying 70% to 75% of the
core. For windings with fewer turns, space the turns with a gap
of approx. the diameter of the wire even if this uses up less than
75% of the core. This generally gives nearly the best performance.

LMR-400 is slightly better than 9913 and doesn't leak.

Uh, that's why reverse sex connectors are used on those things, to prevent
what you are trying to do, which is essentially against FCC rules.

It should work fine, with no degradation from the tree, because the
tree will be outside the antenna area. BUT - I don't see how you can
install it unless you actually climb to the top, which might be risky.
Let us know how the installation goes if you get it up there.

3440. Using CATV outlet's shield as station ground

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-19 23:52:50 UTC
From: Robert Casey <wa2ise@ix.netcom.com>
Message-ID: <3A91B1D2.DD4C78DF@ix.netcom.com>
Source record: 170014

I'm in a 2nd floor apartment, and grounds are a little hard to
get. There's a CATV outlet in the bedroom next to the rig.
In combination with the electrical safety ground (green wire),
it seems to help to also connect to the CATV shield. Before
I connected it, I did measure with an ohmmeter about an ohm
resistance between the CATV shield and the local power plug
safety ground. Two grounds should (because of differing paths)
provide lower impedance to real ground. SWR on my crude
random wire dipole improved a little. No, I haven't received
any CATVI complaints yet.

3441. ATV (UHF) Antenna Design Suggestion?

Hi,

I'm working on all sorts of projects simultaneously. ;)

Can anyone suggest a good ATV antenna for 439.25 MHz,
something with moderately good gain, yet compact and
easy to take down, setup for portable operation?

I would prefer to build rather than buy one.

TNX,

Robert:

What are you doin man? Connecting your transmitter to a CATV coaxial cable!
Might just as well wave a red flag at a bull!

That's just asking for trouble. Sooner or later, the whole neighbourhood
will be beating down your door with TVI complaints.

When on the second floor why not operate without a ground. That's a
perfectly fine option. Radio operators on airplanes and airships operate
radios when they are nowhere near ground. A balanced antenna system simply
doesn't need a "ground".

I repeat... You don't need a "ground" to operate your transmitter if your
antenna is balanced. It should work just fine without a "ground".

You might need a ground for lightning protection, but that's another issue.
Deal with it another way. Disconnect the antenna leads and throw them out
the window onto the ground if lightning storms approach, etc....

Please explain the use of the word "surge"

> current is in-phase with the voltage when there is no significant loss
> (heating) in the line."

Current is in phase with the voltage in an electric lamp circuit, so let
ther be light.
Phase shift between current and voltage is purly down to any net reactive
component. You know that inconvenient bit that has a 'j' in front of it.

Z= R+ jX

Heating in any line will be due entirely to the loses (resitive component
'R')

> Well, had I omitted "significant", some would react with "There are no
> lossless lines". There are plenty of lines that might just as well be
> lossless.

"Just as well" ?
What is being discussed here is that "just as well" component,
small though it is, practical lines always have a little of it.

> I am also amazed at how many who should know better think the
> characteristic resistance of a transmission line is a loser.

Only some of it is.

Zo = R + jX

Some of the people can be right some of the time,
but all of the people can't be right all of the time.

for illustartion consider jX to be zero at some particular frequency
(resonance)
then Zo = R and most of the problem resolves to seeing it in DC terms and
the
line loss is R. for no reflextion to take place the line must be of infinity
length and it will take energy from the source in exactly the same way as
free space continuously and it will be indistinguishable from a substituted
resistor. In fact if some imp cuts the line half way to infinity and
substitutes a resistor equal to the characteristic impedence you will not be
able to detect the difference. Now by some magical means the resistor is

gradually moved towards the source and the line snipped off behind it. now
can the generator tell the difference? The energy is now converted to heat
in the local environment instead of travelling away from the generator for
ever. The difference is only in the fact that the physical resistance has
mass and it is that mass which converts the energy into heat. From the
generator's point of view the resistor and the line are identical they both
take half of the power that it produces.

> Gary also wrote:
> "Be it ever so small (mass heating of antennas and things extracting
> energy from a traveling r-f wave) never the less there will be heating."
>
> Antennas have currents induced by a wave sweeping past.

Only half of the time,
there is also an electric element to the travelling wave,
electrophorus also occurs for the other half of the time.

> Especially when they are well placed and near to being a resonant length.

The antenna and *its associated circuit* come into resonance.

One thing that has puzzled me is the difference of the velocity of the wave
in free space and the velocity of the currents in a medium.
How does the current flow the distance within the medium in the time that it
takes for the free space wave to reverse polarity?
Or does it?

> If they are
> matched to a load they may extract up to half the power from a small
> area of the passing wavefront. The other half will be re-radiated.
> Receiving resistance produces heat.

Yes, I like particularly the words "up to", and Yes ideally it is the
receiver I/P resistance that produces the heat.

That must be true, when I put my hand on my receiver it is hot!

> The reason a microwatt can`t radiate into space and communicate
> indefinitely has nothing to do with sinks soaking up all the energy in
> the wave.

Did I say that it was?

> Every receiver has a sensitivity threshold. When a wave expands to a
> thinness in microwatts per square meter that is too weak to operate the
> receiver, it no longer provides satisfactory reception.

What you are saying I think is that when the signal is no longer significant
in magnitude with respect to the noise voltages naturally present at the
receiver the signal is not recognised as a seperate entity.
It is still present and suitable bandwidth reduction will if you know where
to look for the signal will reveal it.

Because, unlike noise it carries on in an un-stochastic (regular) manner.

Radio Astronomers have long used long time constant integrators to detect
the tiny signals from distant galaxies (excess noise).
However this became self defeating in the case of the pulsar, the modulation
was concealed due to the excessive time constants then used.
But I digress.

> If we could concentrate radio energy into a column that would not spread
> out, we could aim it at any unobstructed point in space and communicate
> using extremely small power. It`s the spreading of the wave that`s our
> downfall, not absorption.

In the case of very shortwave electromagnetic wave generated by a laser this
is demonstrated to be true.
To do the same thing with the sorts of waves with which we play would
require a parabola of as many wavelengths apperature. (Somewhat larger than
the Earth)

Diameter of Laser x (Radio Wavelength/ Light Wavelength)
0.01m x (80 / (8 x 10^-7)) = 10^6 m diameter for 80 m band.

However the problem then becomes one of pointing the concentrated beam with
sufficient accuracy to be useful.

Was it Hercules or Atlas that was looking for a platform?
Not that it would have done either of them much good the trains aren't
running yet again.

As I was going up the town
I met a train that wasn't there.
It wasn't there again today-
I wish to God they'd go away

If you want a train look for a crash.

I'm not sure what the problem is Roy, but the Q values are
unrealistic. This is especially true above about 1/2 of the
self-resonant frequency of the inductor.

While Reg's program (even solenoid2) shows Q steadily increasing, real
world measurements show the parallel resonant Q peaks at about half of
the self-resonant frequency and then smoothly and rapidly decreases as
the self-resonant frequency is approached. Of course series resonant
systems peak much lower.

It is also very easy to "design" an inductor with a Q of well over
1000, yet I have never seen one over the high 800's (although there
might be some out there).

I assumed the error was in how it handles the capacitance, but it
might be anything. Anyway, as long as you stay away from anywhere
near the self-resonance it is a useful program. Except the damn
numbers are all in some odd meteric form, instead of the US standard.

Indeed Steve VE9SRB, however from the generators viewpoint, it only sees the universe looking up that bit of copper wire, it knows not the difference, it still has to give up half of the energy that it produces; whether it be as part heat and part wave going off into space forever, or as all heat in the case of a dummy load, to the generator it knows no difference.

Where things get a bit tacky is if some large reactive component that shifts the phase of the current with respect to the phase of the voltage is introduced.

The current in vaccuum latching relays is very high.

The choke has to stand-off high voltage.

You have almost the problems you would have with a trap.

Mark,

CATV coaxial hardline is very easily obtained from your local cable company. You should be able to come up with 200 feet of .750 hardline or larger for next to nothing. As for the connectors you will have to improvise or buy expensive connectors, but if the cable is free what the heck. Get the underground varitiey and it can be buried for a neat installation. I used 350 feet of the stuff for many years on hf. It is 75 ohms, but if you worry about the minor mismatch just build a unun or purchase some sort of matching balun/unun. I spent 20 years in the cable biz and it is good stuff. The loss on HF is very minor, and if you have a good coaxial remote coax switch at the tower you can also use it for vhf.

> dissipation of EM energy in the form of "heat".

From the narrow world view of the generator it can tell no difference.
All that it knows that in a matched condition it has to give up half of the
nergy that it produces.
It's a bit like a tax payer, who knows that he has to part with some of his
hard earned income and then has absolutely no control over how the
government of the day wastes it.
(The masculine case shall include the femanine; unless otherwise stated)

> Assume a perfect isotropic radiator. Field density (or intensity)
decreases
> with distance away from the radiator because the total radiated energy is
> distributed evenly over a sphere of increasing radius.

It was smart of Newton to spot that one.
Oh for w afew simple drawings the square law loss is so much easier to teach
with a diagram. ASCII art just won't do justice to this one in particular.

> This reduction in
> field density is not really an attenuation or "loss" of energy. At any
> distance, the total energy distributed over the sphere remains unchanged.
> We define this phenomenon as "path loss" only so that we can describe the
> decrease in the field density in terms of distance and wavelength.

Precisely it is the diminution of field density available to the effective
apperature of any receiving antenna place in its path. It is of course loss
in the true sens because the receiving antenna can not make any use of the
other part of the 360 stradians that make up the surface of the sphere at
that distance from the transmitter. All of that signal is lost, unavailable
for reception. From the Receivers view point it cares not if the lost signal
energy was gobbled up by a resistor as heat or is yet carrying on into the
void of infinite space, that energy fraction from the transmitter is
unavailable for communication.

On these grounds we are justified, (on the square),
in calling the path loss a loss.

Loss that which is unavailable.

Using theCATV shield is NOT a good idea.
#1. CATVI will occur
#2. Strong front end overload and damage to a neighbors TV can result in a lawsuit.
#3. Cable systems use the HF bands for their return path and you will interfere with them and they will come a looking for the problem.
#4. Not all cable companies use proper grounds, most are bonded with the power, and telco grounds. (more problems)
#5. If you must, lay out radials around your rig, but look out at night when going to the bathroom.... :-O
#6. Common Sense?

Yes indeed Alex! I bought a MA5B too, partly because of your fine review.
The antenna itself works as expected - a good compromise, if you can't put
up a bigger antenna.

The cable ground should be bonded with telco and
power grounds at the service entrance. Why?

Lightning. Let's say a strike, or near-strike comes
in via the power line. All those electrons are looking
to get away from each other. Where can they go?
To your telco & cable grounds. How do they get there?
Well, if you bond at the service entrance, there is only one
ground. No problem.

What if you didn't? Well, what is the easy path from
the power mains to the cable ground? It's right through
your tv set and/or cable box. Toast.

The tree is only about 8 feet tall so I think I'll be Ok up there. :)

It does have a clear takoff to the horizon over about 200 degrees arc
though, and a vertical has worked reasonably well in a similar spot at a
similar height. I'm in the East Anglia region of England where the terrain
is pretty flat.

> Let us know how the installation goes if you get it up there.

Will do.

That isn't a "study", its a guess based on a NEC-2 model. Real world measurements disagree with the conclusions in that article.

As a matter of fact, VK3AX (the fellow who is reported to use the small system calculated as being better than 30 radials on the ground) is constantly beat by VK3ZL into the USA. VK3ZL uses a 40 foot top-loaded vertical with **25 radials** laid on the ground.

The difference in the signals from VK3AX and VK3ZL is striking, almost ten dB on average. I can hear VK3ZL virtually every morning no matter what conditions are, and only hear the station using the small ground a few days a month (despite the fact he meets almost daily with others in VK on a certain frequency).

The stark contrast in signals is enough to convince me small ground systems are far over-rated.

Gary Peach wrote:
"Please explain the use of the word "surge".

Deposit a "potential difference" across a transmission line. There will be a difference of potential between the points of deposition and other points along the line. Current must flow to equalize the potential difference.

There was no current before charge was deposited on the line. Charge deposition abruptly initiates current. Thus we have a surge.

What is the magnitude of the surge current? It depends on the construction of the transmission line and the potential difference (voltage).

The ratio of voltage to current is named resistance when the current rises in lock step without delay just as the voltage rises. There doesn`t have to be any dissipation.

In the case of a surge on a transmission line, with insignificant loss, regardless of the magnitude of the voltage, the current will have a magnitude which is a constant percentage of the surge voltage. This voltage to current ratio is called the surge impedance, surge resistance, or characteristic impedance of the transmission line.

Hi Gary:

I fully understand why its called "path loss". Most people understand the end result. Describing the process is where problems usually arise. My comments were directed at your statement "if there is no dissipation there is no propagation". Dissipation of energy in the form of heat is not a requirement for the propagation of EM energy. It may however, be part of the propagation process. The distribution of energy in space as it travels away from a source is not a heat dissipation issue as your statement might lead some to believe.

Hi Gary:

From the generator's perspective (in the steady state), it sees an effective load impedance at the transmission line input. If we do not want to look beyond this point that's fine. If however, we want to understand the process of wave propagation in the transmission line and radiation from the antenna, we need to look beyond the generator's viewpoint.

Whether the generator gives up "half of the energy it produces" or some other level, is entirely a function of the generators internal components and the effective load impedance it sees.

Gary Peach wrote:
"What is being discussed here is the "just as well" component, small though it is , practical lines always have a little of it."

"just as well" implies loss in a transmission which is insignificant. This is possible. Lines exist which are wavelengths long but still have very small values of series resistance and shunt conductance as compared with their surge impedances.

There is no need here to complicate a discussion of impedance matching beyond saying we are going to correct the power factor or tune out the reactance.

Hi Gary:

The characteristic impedance of a transmission line Zo is, as you state, generally of the form R + jX. More appropriately, it is defined as Zo = Ro + jXo. There is however, more to understanding the loss of energy in the transmission line than just looking at Ro alone. The line loss at RF frequencies is not simply given by R (Ro). Different transmission lines with the same Ro may have different loss factors.

The loss factor for a transmission line is given by alpha which is expressed in nepers/meter. Loss in the transmission line is always a function of unit

length. The resistance of the transmission line R, is expressed in ohms/unit length. The real part of the characteristic impedance of the transmission line Ro, is expressed in ohms.

In general, the transmission line loss factor, alpha = 0.5 (R/Ro + G/Go) where G and Go are the conductance of the line/unit length and the conductive component of Yo in mhos, respectively. Ro and Go can be written as functions of the basic transmission line parameters R, L, G and C.

Let`s look at it another way. Resonant lengths of transmission lines can be a wavelength or fractions thereof. Series resistance and shunt conductance can be negligible.

Let`s look at an infinitely long transmission line with negligible losses. It was Reg Edwards, I believe, who said you could just apply your d-c ohmmeter to such a line and read its surge impedance.

Gary Peach wrote:
"The energy is now converted to heat in the local environment instead of traveling away from the generator for ever."

The above is a correct statement of difference between a dummy load and an infinite transmission line. It misses the point that electrical energy is converted to heat by the dummy load but remains unconverted in the lossless transmission line.

Best regards, Richard Harrison, KB5WZI

Gary Peach wrote:
"Only half the time (A wave sweeping past an antenna induces a current), there is also an electric element to the traveling wave, electrophorus also occurs for the other half of the time."

I`ll quote Terman from Page One of "Radio Engineering":
""Electrical energy that has escaped into free space exists in the form of electromagnetic waves. These waves, which are commonly called radio waves, travel with the velocity of light and consist of magnetic and electrostatic fields at right angles to each other and also at right angles to the direction of travel."

Study that. It says it all.

Gary Peach wrote:
"How does the current flow the distance within the medium in the time it takes for the free space wave to reverse polarity? Or does it?"

It does not. Like charges try to keep their distances from each other. They therefore pass along a shove without migration.

When a passing wave induces current, the current mimics the wave sweeping past an elemental section of the conductor. but a phase difference can occur.

Ben,

I read all the other posts and thought I would add my $0.02. The
following
is how I understand a loop antenna, which could very well be wrong, and
a
description of the one that I made and used.

The intent of a loop antenna is to maximize the enclosed area. A circle
is the best, but that would require and infinite number of tie downs to
make that shape. A compromise is the square or rectangle, with the
square
being the best choice. Of course a triangle could also be used. But, if
all you can use is a rectangle, use it. Just remember that as the short
dimension of the rectangle gets smaller and smaller ,the antenna starts
resembling a folded dipole.

If a square shape is used, each side should be 1/4 wavelength at the lowest frequency of use. The total length would be 1 wavelength. I think the "total length = 1005/frequency(MHz)" formula should work. The exact length, at least in my experience, is not that critical.

I built one for 40 Meters and used about 140 feet of wire. For 80 Meters you will need twice that. I used a #14 stranded wire that sells in Radio Shack in 70 foot rolls. Four roll should be all you need. While you are in Radio Shack, they also carry ceramic insulators for the corners. I used two of the 70 foot rolls and made a sorta/kinda rectangle.
Three of the sides were out in the open but one side ran real close to a rain gutter. The whole thing was only about 15-20 feet off the ground.

The feed point was near a window and I used about 15 feet of 300 ohm twin lead. You should be able to use any kind of balanced feedline from 300 to 600 ohms. I tied the feedline to the balanced output of my tuner. It may have been better to use a 4:1 balun and then feed the balun from the coax output of the tuner.

When I built my loop antenna, I was portable and didn't have any test equipment available, however it did work very well. It was nice and quiet, noise wise, and sensitive. I found that it tuned up well on the fundamental design frequency and on all harmonically related bands, i.e. 20, and 15 Meters. I didn't try any other bands at the time but it should also work on 10 Meters.

I was only running a Heath HW-8 at about 1 watt output and managed to get a I1 station. It was a very short lived contact, but he did get my call correct. This led me to believe that the low angle radiation is fairly good even at the low height, 15-20 feet.

Your dimensions of "14x67 feet" will be a little short for 80 Meters but should be enough room to construct a 40 Meter loop. It might work on 80 Meters if you short the feedline wires together and operate the antenna as "end feed". You should probably get it as high above your mobile home as possible, to minimize any interaction.

I intend to re-construct mine and do some more testing. It did seem like a nice simple antenna that worked very nice on multiple bands.

Hi Gary,

There's something here that few would pick up on. The velocity of the wave in free space and the velocity of the wave in a media different from free space are accountable by the media that is different. This is simply Snell's Law.

However, you slide into the speed of the current in the media and try to correlate it to the speed of the wave in free space. Two very different beasts. Let's simply stick with one media when we examine the speed of the wave and the speed of the current.

If, perchance, the speed of the current exceeds the speed of the wave (there are instances of this), then we find ourselves as witness to a new radiation - Cherenkov radiation, which appears as a blue wavefront much in the same style as the bow wave from a fast moving boat.

And then you slide into "distance." The only current that comes close to light speed over any distance is found in the conventional amplifier tube between the cathode and the plate. Current truly flies here in stark contrast to the "induced" current outside of the tube that's physical distance of travel over time is on the order of cM/second. That is, the speed of any electron in the current outside of a tube. The effect of the current movement propagates at the same near light speed, but the two speeds (the electron, and its effect) are distinctly different.

Now the really remarkable fact about this last near light speed current phenomenon in a tube is that it conforms in every sense to meeting a "dissipative" resistance INSIDE THE TUBE. That is, Plate Resistance is as real as a chunk of carbon and produces the heat to prove it. Back when Hams built their own rigs, you can be sure they were aware of their plate "dissipation" limit for ANY particular tube they designed around. Some may confuse the heat shedding of the plate as simply the process of being illuminated by the filament. That is,

a coffee pot gets hot because of the stove's burner - heat transfer by conduction, convection, or radiation.

In a sense, the plate of a tube also absorbs heat in the same manner (unless we have a tube with a cathode covering the filament) - however, this source is only a minor contributor to the total heat load suffered. The major heat load comes from the deceleration of electrons as they attempt to penetrate the metallic lattice of the plate (electron penetration rarely succeeds in traveling more than one to three atom's thickness). The deceleration from near light speed to a crawl in the space of angstroms yields heat - this is classic Newtonian Physics. Hence we have a paradox wherein the seemingly low resistance metal plate in fact exhibits the loss of carbon (or worse).

This paradox is a hard swallow for many (especially those who try to argue the source's non-dissipative characteristic). Those who choke generally sputter about perfect switches and current conduction angle. If researchers who attempt to measure the Z of a real transmitter as source fail to find a real R component strongly correlated to the specification for Tube Plate Resistance, then their method is highly suspect.

Check with local electronics outlets that sell TV antennas. If they sell any Rohn stuff at all, they should be able to order anything you need. I stumbled across such a place about 50 miles from my home, and he was happy to order what I needed (Rohn 25 top section). I paid the full retail price, but HE picked up the shipping. A very good deal indeed. I had first tried various ham outlets who would ship to me, but it would have cost me as much for shipping as the piece cost.

Hi Cecil,

Yup, reported that fact here back last year when the U of W (my alma
mater) slowed it down to 45 mph. Recent news shows that a light pulse
train can be trapped in a dense media and then successfully prodded
out by a second, differentiable pulse.

The purpose of this is for optical computing and bus control. The
ability to store a segment of light is equivalent to storing data, the
purpose of which (for the practical side of this) is to allow routers
to parse the packets optically without turning the optics to
electronics and then back to optics. The turn-around conversion
process is death to the boon of fiber optic connectivity.

The amount of radials needed for an elevated ground plane depend on the height of the antennna. Also there are a few statements in his html that I don't agree with. Such as :

4.Large numbers of radials are not required for elevated groundplane systems. Three or four radials are sufficient, doubling the number does not double the efficiency.

This is malarky. Again, depends on the height in WL. Only if the antenna is at a 1/2 WL do 4 radials provide a radial system equal to 120 radials on the ground. At 1/4 WL you will need appx 10 to do the same. At 1/8 WL you will need appx 60 to do the same. On an average , every time you double the radials at a certain height, you gain appx .4 db or so, so only his last statement is accurate.

5.The elevated groundplane system is more efficient at lower frequencies.

I almost choked when I read this one. The elevated ground plane is equally efficient on any freq as long as the antenna is at the same height in WL. IE: a 1/4 gp with 4 radials on 160m at 1/4 wl up will have the same efficiency as a 2m 1/4 gp with 4 radials at 1/4 wl up. Of course on 2m a 1/4 wl up is 19 inches. On 160m a 1/4 wl up is 125 ft or so. MK

Looking for a base Ringo capable of 440 and a used MFJ antenna tuner. Also have plenty of tubes to sell and lots of equipment I'm getting rid of and upgrading everything. Also collecting vintage grandfather clocks for top dollar, will pick up in Oh/Pa/Ky/WV area. Autographed Nascar jacket signed by Dale Earnhardt, serious inquiries only.

In East Anglia 8 feet is tall. The land around here is so flat that an anthill is a mountain! Unfortunately this means that there's aren't many hills to go buy a house on to get a good VHF site. :(

Cheers,

Mark.

p.s. You couldn't spare one of your pine tree could you? :)

Hi Mark,

I've followed the other entries into this thread of yours and if, as
you say, your "tree" of 8 feet is no stellar grower, then you probably
can get away with what you describe.

If on the other hand, the tree grows as do most trees, it will
probably penetrate the skirt and enter into the region that lies
between the skirt and the disk. This is not a favorable condition and
it is almost certain to happen - sometime. However, as it will
introduce loss, it could easily appear to "improve" performance (at
least the match part, not the radiation part). Don't be fooled by SWR
when it starts measuring that tree as a dummy load.

You also have to be aware that if you are strapping a mast to the tree
to support the discone, then you may easily kill the tree by
compression of its cambial layer beneath the bark. As the tree grows,
it also expands and if it has to work against a hoop (the strap around
the mast and the trunk), that hoop will strangle the growing tip. the
correct manner is to use stand-offs that screw into the trunk (and
seal those entry points against weather and insects). The screws (or
lag bolts) should be long enough to allow bark to grow around them
without compressing against the mast on the standoffs. For such a

small tree, this seems to be an unlikely design angle.

Rick, K1BQT wrote:
"Perhaps Walter does have something to tell us." (Whether the generator gives up "half of the energy it produces"---)

In the recent thread example of a receiving antenna it works that way. The receiving antenna extracts energy from a radio wave sweeping by. The best it can do is deliver 50% of the energy it gets from the wave into the receiver input. To do so it must be perfectly matched, antenna with receiver, that is. If the match is less than perfect, more than 50% of the energy is lost to the receiver input. Energy in the antenna system which is not absorbed in the receiver input is simply re-radiated.

Best regards, Richard Harrison, KB5WZI

I find it interesting the "study" you quoted warns at the end it may
not be correct.

Well, I A-B'ed two antennas here and at another location and found
four elevate radials about even with 16 laid on the ground, and sixty
radials on the ground was about 5 dB better than the four elevated
radials.

A few BC stations have found the similar results.

As for a "quality study", these has been none as far as I know. The
basic problem is no one is all that interested except Hams. All I have
ever seen, and I've watched this extensively, is NEC models supporting
the claims that four radials are enough.

Everyone I know that has tried both systems at one location has found
a small elevated system lacking in performace.

>so. MK

I found the part where he said 120 radials are necessary when on the
ground somewhat odd. It was almost like he was trying to exagerate the
work needed for a conventional system.

Anyone with any sense at all for this problem knows that once you get
to 50 or 60 radials efficiency is almost 100%. Even 30 radials gets
you pretty close to the flat part of the efficiency curve.

Even if all other things were equal, which they are not, I'd never
put up with the mess of having four wires that are radiating and
coupling into everything around them. Just the complexities of not
being able to properly ground the system for lightning, and the fact
it would only be good on one band, is more than enough to chill me on
the idea.

Greg Blair wrote:
"Has anyone ever observed interference between a X band, 3 CM RADAR transmitter and an L band GPS receiver antenna due to close proximity?"

Radar interference can irritate. A big radar pulse doesn`t need to be close geographically or in frequency to produce interference.

My company had a division office on the Houma, Louisiana air field. We had a 33 MHz company FM base station on a tower a couple of miles away from the airfield to get the height we needed which is not allowed at airports. We had a wireline control of the base station.

Every rotation of the FAA`s radar swept our radio tower and broke the squelch on our FM radio with a loud audio buzz. We could have used tone squelch to overcome the repetitive buzzes from the radio control console, but the office staff was content to turn down the volume and live with the regular noise spat from the loudspeaker. They seldom if ever missed a call in spite of the reduced speaker volume. It`s called adaptation.

I am putting my shack together in my walkout basement. Here in Minnesota, it is really COLD right now, so putting in a ground rod outside is not an option--probably at least a couple feet of frozen soil.

However, I could put the ground rod under my shack. To do that I would simply drill (or in this cased hammerdrill) a 3/4" hole in the basement floor, then add some water to the hole, and pound the 8 ft. rod in.

Would such an underground ground work well???

Thanks

Mike

Mark and Raymond,

If you are using the 5/8" dia stuff, here's a cheap but effective way
to connect it. First split the outer metal cover just to one side of
the center conductor about 1 1/2" back with a hacksaw. Then use a torch
to burn out about the same distance/amount of the dialectric. Clean out
whatever material may be remaining inside the metal cover. Insert one
of those double female "barrel" connectors into the space making sure
that the center conductor is inside the barrel about halfway thru. Then
use a small hose clamp to tighten the outer cover down onto the "barrel"
connector. Make certain it is tight and check for continuity. The clamp
will tighten the metal cover down firmly (the two split sides) and
you can screw on a PL 259. Hope that helps.

I would like to construct a telescoping PVC support for a Windom antenna.. Will top out at 40 feet. So the question is: using Schedule 80 PVC , what sizes will properly match up, with the O.D. of one segment sliding into the I.D. of the segment beneath it.

I do want a PL 259 to be able to fit inside the top section. (3/4" I.D. ??)

I looked for a resource on the web but couldn't find one..

Bill..

I would use the drill outside with a long auger bit to get the hole started.
With an outdoor hole, you won't have to add water when there is adequate natural
precipitation.

Thanks for your comments about radials number.
What about using a 7,5 meter vertical radiator? I think It can works for frequencies higher than 10 MHz, and its a compromise for 7 MHz. I want to adapt impedance with a remote L network tuner.

Iron Pipe Sizes are the inside diameters.

You could use 4", 3.5", 3", and 2.5" with some reducers and bushings to get to 0.75" at the top.

You might need some cable grease to make it slide.
There will probably be a static electrical charge from the friction when you extend or collapse it.

Lets carry that contention a little further we'll flatten out the conductors into sheets and wind then up into a tube and we will still get an exponentially decreasing current when we apply a DC Voltage.

If we leave the distant end of a transmission line (co-ax, open line) open or shorted then a delay time later the applied voltage will double momentarily as the sign is reversed at the open/shorted end.

This is the Basis of a PFN (Pulse Forming Network) for deriving a very high voltage pulse to modulate a magnetron.

If we carry this idea a little further and use the step input of voltage as a test signal we can construct a time domain reflectometer.

For those unfamiliar with this type of instrument, a voltage step is continuously applied to the line under test, on the cathode ray display of the device pulses of reflected energy show on the time trace whose magnitude is proportional to the miss match of the discontinuity and whose time delay from the original step transition is proportional to twice the distance from the instrument to the discontinuity multiplied by the propagation velocity of the line.
If the line is left unterminated the double voltage is reflected diminished by twice the line loss (VE9SRB's alpha using natural logarithms e^(-alpha))

Oh! for the ability to display pictures!
At this point I would return to the VSWR measurement technique more familiar to Hams and show a plot of voltage minima and maxima as a voltage probe is moved down a long line terminated in a miss-match.

The maxima gradually become less as we approach the (?)
Well I'll leave that as a question for anyone to answer
Is it
a. approach the load?
b. approach the generator?

Thank you Richard that is exactly my point, perhaps I didn't make it very clearly or the limitations of semantics obscured my intent.
As far as the generator looking out onto the universe through its narrow portal the transmission line it knows not whether the child which it has spawned goes forth bravely into limitless space or is consumed in some devilish fire. It only knows that when the child left it left as fast as it could go.

To the generator the dummy load placates the child as easily as the caverns of free space.

He was only repeating what James Clerk Maxwell (1831 - 1879) said years
before in mathematical form, so it is really hear-say evidence. ;)

Frederick Emmons Terman Sc.D.
goes on in 1937 to say:

" ... travel. If these electrostatic and magnetic fluxes could actually be
seen the wave would have the appearance indicated in Fig. 1. One-half of the
electrical energy contained in the wave exists in the form of electrostatic
energy, while the remaining half is in the form of magnetic energy."

Really Richard, if you are going to quote standard texts you should not edit
them to make some conceived point.

Ah I see it now and resort to an analogue.
An Engine reverses sharply and stops the trucks transmit the shove clank clank clank without each individual truck moveing out of it's position.
If at the same time the shove were imparted to a free rolling ball along side the trucks would it keep pace with the clanks?

Of course we can not answer confidently for the ball as the parameters of the rolling surface have not been defined, if it is on sand the ball will shortly come to rest, however if it is on a pair of knife edges it will go some way gradually coming to rest possibly at some point further from the engine that the length of the train.
But the thing that interests me is how its relative position keeps pace with the transmitted clank.
Anybody that has lived close to a shunting yard and has lain awake in the dark of night listening to the sounds of industry, will recognise that they witnessed for themselves the reflection at the unterminated end of the line of trucks as the remnant of the clank travelled back towards the engine.

> When a passing wave induces current, the current mimics the wave
> sweeping past an elemental section of the conductor. but a phase
> difference can occur.

Yes now that phase difference is of interest, from Lenz's Law the induced current will have opposite polarity, How now does the couple between the freespace wave and the trapped wave react?
Is it a clever compromise here that produces an ideal AE?

I say naturally because the noise voltages occur in "ALL" receivers without
any effort on the part of the user.
That no matter how hard the user tries he can not completely eliminate those
noise voltages even should he resort to a hydrogen refrigerator and the
implied ex-pence!

> Yes. I said a receiver has a sensitivity threshold. It could be set by

In fact it is set by both, neither noise source is removable.
We have to live with it.
In it's, (the noises), abscence almost zero power would be useful for
communication at infinite distance.

I introduced that as an old lemon,
If the number of receiving AE in the city nearest the transmitting AE soaks up the transmitted energy, will the distant receivers loose signal?

> Too many TV antennas in an area are more likely to produce ghosts.

I would take issue with that one Richard assuming that the additional AE soak up the signal there is less available for reflection.
The one thing that you can be sure of that the increase of sets will increase the revenues raised, by the Industry, the advertisers, the broadcasters, HMG.

I'm not too keen on lemons myself. ;)

At that point the PD becomes an EMF

If you connect noting across the terminals of the battery it will remain a
PD.

> There was no current before charge was deposited on the line. Charge
> deposition abruptly initiates current. Thus we have a surge.

Yes, that is clear Richard.

> What is the magnitude of the surge current? It depends on the
> construction of the transmission line and the potential difference
> (voltage).

One might also what is the duration of the current, as I presume that you
are considering the DC case at this point in the discussion. An
instanteneous current would also flow if the EMF was applied to the
terminals of a capacitor. (no resistive element required) All done it many
times with the multimeter and the suspect capacitor. Kick, decay.

> The ratio of voltage to current is named resistance when the current
> rises in lock step without delay just as the voltage rises. There
> doesn`t have to be any dissipation.

The current will not remain constant it will decay exponentially so we can't
simply apply Ohms law.

> In the case of a surge on a transmission line, with insignificant loss,
> regardless of the magnitude of the voltage, the current will have a
> magnitude which is a constant percentage of the surge voltage.

But the Voltage is not constant

>This

> resistance, or characteristic impedance of the transmission line.

I Think I understand what you are describing as the surge resistance but
this is only a transient, and is not therefore equivalent to the

Characteristic Impedance of the transmission line.
Drawing this comparison is the sort of mistake I might expect a computer to
make, you have failed the Turing Test Richard. ;)

Agreed.
That could be a loaded statement. :)

> The loss factor for a transmission line is given by alpha which is
expressed
> in nepers/meter.

Under the SI metric system yes, it may also be expressed in dB per foot if
you use logarithmes to base 10 instead of natural logarithmes to base e ,
and the Imperial System instead of the Metric System. Text books wil more
generally when covering this subject at this depth will be using natural
logarithms and values normalised to units of PI. I can hear Napier's Bones

clanking away in the background even now, that is a sliding rule.

>Loss in the transmission line is always a function of unit
> length. The resistance of the transmission line R, is expressed in

written
> as functions of the basic transmission line parameters R, L, G and C.

Yes I agree with that.
If only we could show pictures, once again I would show the plot of a
voltage standing wave with a voltage probe moving down a long line,
waveguide. The maxima of voltage diminish the amount by which they diminish
is due to the line loss of which you speak. The magnitude of the peak is
primarily due to the mismatch of the terminating impedance. Were the
terminating impedance is a perfect match the maxima and minima become equal
and the voltage probe now traces out a straight line representing the
voltage on the line which gradually falls towards the load. This slope,
(fall off of indicated voltage), is the line loss of which you speak.
Oh! for pictures, it would be so clear.

The response of a TDR to a lossy line is a rising, not falling, value.

Here's a way to understand why. If the TDR step encounters an open circuit, you'll see a positive reflection come back which is equal to the amplitude of the original step (assuming the step generator source resistance equals the line's Z0, the usual case), for a total amplitude after the reflection of twice the initial step value. Now imagine a very long line which has loss, so that essentially none of the signal returns, and the DC ohmic resistance is very high. Initially, the TDR sees Z0, but the resistance increases as time goes on. In the limit, after a great deal of time, it'll see the same value as an ohmmeter. If the line is open, this will of course be infinite. If the line is terminated in a short circut, the resistance looking into the line will be the ohmic resistance of the line itself. For a long, lossy line, this will be a much higher value than Z0.

Reg is correct in saying that you could measure the Z0 of an infinitely long line with an ohmmeter. But only if the line has absolutely zero loss. Otherwise, you'll measure a resistance that increases with time until it eventually reads open. For ordinary cable, I imagine this would happen much faster than the meter could respond, but you'd have to have an impossibly long piece of it to do a test.

Not if it's DC Grounded.

But, the 14AVQ is not (I wouldn't think, given the age of the antenna) a
DC grounded antenna

Good point. I'll have to remember to adjust the pole a few times a year.

> You also have to be aware that if you are strapping a mast to the tree
> to support the discone, then you may easily kill the tree by
> compression of its cambial layer beneath the bark.

Not a problem. The "tree trunk" is about 9 inches away from a small concrete fence post. I'm currently using a pole strapped to the fence post using hose clips, which from a mechanical point of view works fine but it means that the higher up the pole you look the further from the "tree" it is so it's very visible. I plan to somehow mount the pole on the fencepost far enough out from the post that the pole is parallel to and only an inch or so away from the "trunk", so running it up inside the branches nicely out of sight. I'll probably do that with the brackets and wire normally used to lash a pole to a chimney, or at least something along those lines. The tree/plant won't be supporting the pole in any way.

Cheers,

Mark.

I have seen similar antennas on cars from towns that are known to have
an AVLS system. That would be my first guess. I have seen similar
antennas on vans owned by nationwide courier companies like Roberts
Express as well.

I tried it and found 40ft to be too long for reasonably sized PVC.
I switched to 2x4s and 2x2s.

Gary Peach wrote:
"The current will not remain constant it will decay exponentially so we can`t apply Ohm`s law."

Reg Edwards was applying an ohmmeter to an infinitely long lossless transmission line.

The line has distributed inductance in addition to distributed capacitance. We are not just charging a capacitor here.

The inductance allows current to rise but inhibits it. Capacitance readily accepts current but inhibits voltage rise.The long line with distributed iductance and capacitance does not appear as either an inductance or a capacitance. It appears as a resistance. Not the kind that eats energy, only the volts over amps kind.

There is no charge-up exponential decrease in current into the infinite lossless transmission line. Reg`s ohmmeter would continue supplying current into the line at a constant rate and the line would continue carrying the current away. The rate at which the line accepts current is only determined by its surge impedance.

The line is lossless so there is no exponential decay along the length of the line.

Best regards, Richard Harrison, KB5WZI

Gary Peach wrote:
"---if you are going to quote standard texts you should not edit them to make some conceived point."

It is impractical to quote the whole book. I agree with all of it. I don`t aim to twist Terman`s meaning.

I agree with you that half of the wave`s energy is contained in the E-field and half is contained in the H-field. The point is they are in quadrature. One field is not exciting an antenna for awhile, while the other field rests, and then alternating with the other field.

Best regards, Richard Harrison, KB5WZI

Mike,

I asked the same question recently. The problem with a ground rod under the house is that for a ground rod to work well, the soil around it needs to be moist. Hopefully, that is NOT the case with the soil under your basement floor.

73,
Mark

Pete, there's a flaw in your first line. Regarding predicting accuracy I don't state say what my programs do. I leave it to users to discover for themselves they are accurate enough for the intended purposes.
==========

>... however you are testing my assumptions about your good work now, because... from your observations below, I see that - Your pique is showing...

==========

Not pique - just tiredness caused by evasive replies.

==========
>
> How about sharing with us some of your algorithms/formula and comparisons to
> actual measurements.
>
==========

I can assure you, you would be unable to understand the source code and and follow the track of reasoning! After a few months absence I have difficulty myself. There would be more quibbling and haggling and sidetracking between unqualified participants than has occurred with Conjugate Matches and Fractals put together. This would wreck the confidence which has accumulated during the last couple of years. In any case this is a radio amateur newsgroup - not a mathematics and computer programming training course.

==========
>
> It's unfair of you to ask Tom to make measurements to verify
> your programs for you.
>
==========

There are no rules to this game. ;o) I did not ask Tom to veryify my programs for me. I asked him to numerically quantify his criticisms rather than voice an opnion. In other words - what was

the source of HIS data with which he had compared programs. Everyone already knows the source of MY data - it's the programs themselves. And his criticism was of only one of the computed parameters in one of 35 or so programs.

To clarify your thoughts -

Tom originally said that all computer programs over-estimate Q and max Q occurs when coil turns are almost touching. He said this was due to programmers ignoring the effect of capacitance between turns. He specifically included my programs with the others. (I have never seen any others myself.) But he did not state what HIS measurement standards were.

I asked him to look at SOLNOID2 for the wire spacing at which maximum Q occurs. In another branch of this topic he then withdrew his criticism about my calculation of Q and replaced it with a criticism of the International Standards of Measurements. He also withdrew his view that Q decreases with close spacing because of increased capacitance between turns.

Tom did not replied to my question as to whether he had heard of the formula I gave which relates Q, L and R to stray capacitance. In reply to your request for the secret "algorithms" it is used in SOLNOID2. It implies that the effective Q of a coil depends on whether the coil is used in a series LC or a parallel LC circuit. Tom did not mention that important (in the present context) fact.

For example, the effective Q of a coil is lower in a Pi-match output circuit than the same coil when used in a tuned tank circuit.

A comment on Q measurements -

If, as Tom says, Q values at HF cannot be greater than 1000 or thereabouts, then to obtain any degree of accuracy the Q of the conventional Q-meter itself would have to be several times greater than that and accurately known. And to correct measurements calculations are unavoidable.

Working values of Q when inside a screening enclosure or adjacent to poor materials may be appreciably less than values measured on an isolated coil. Calculated values obviously apply to isolated coils. It is important to note it is not the coil which gets warm under enclosed conditions but the enclosure. When a magloop or dipole is near the ground it is not the magloop or dipole which warms up but the ground.

But accurate values of Q are not required for engineering purposes. It is sufficient to know Q is greater than some minimum value and calculated values are good enough. Indeed very high calculated values may be more accurate than the measured variety.

How is the intrinsic Q of a Q-meter determined ?

The only other use for Q values is to provide an enduring topic for
argument between perfectionists (bless them) on this newsgroup.
;o)

In the same spirit, I have disagree. If you look at the following web site...

http://www.gesupplylight.com/

...you will see that General Electric (GE), the largest supplier of lighting solutions in the United States, calls it a "lightbulb."

In addition, lightbulb is one word, not two like you show it above. Again, GE, the acknowledged leader in this field, uses "lightbulb" throughout their web site.

To verify both of these claims, here is a quote directly from their website...

"We've made buying GE lightbulbs for
your business or facility easy!"

Now, are you disputing the words of this wonderful company, Dave? ;-)

Reg`s statement: "It`s an old wives` tale that Q is poor when most of the capacitance is of the parasitic variety." evoked response.

My response concerned a self-resonant coil as compared with coils using external capacitors in parallel with the coil to resonate at at the same frequency.

I believe that Reg noted that in a series resonant circuit, the parasitic capacitance increases current in the coil by the amount of circulation between itself and the coil. Or, maybe his point was that the parasitic capacitance vitiates some of the inductance. I don`t remember now exactly what his response was, and I`m not clear how Q might be improved by parasitic capacitance.

I rediscovered that Terman has done all the work already and published it on page 67 of the second edition (1937) of his "Radio Engineering". As Reg might say: Maybe someone else did the work and Terman just copied it. If so, Terman checked the work and found it believable.

Terman doesn`t say Q is poor when most of the capacitance is of the parasitic variety. Terman does say: "It is to be noted that the apparent Q of a coil is decreased by self-capacitance."

As I sit here amidst the snow and fog, I am dreaming of better days.

I'm planning to get a QRP rig that I can carry with me on hikes. I've read a lot of articles on the Adventure Radio site about some of the elaborate antennas some take into the backcountry. But, I'm looking for simple and fast -- no wire beams, vertical arrays, etc.

Right now I'm thinking of making a telescoping walking stick to use as a mast for an inverted V on 20m. The apex would be up at maybe 15 feet with the ends at or near the ground. A rope would be the third guy line. The whole thing ought to go up in a minute or two.

What do you think? Any other ideas? Again, I want something quick and simple. Oh... I'm often hiking in country where the are few if any trees so I'll have to carry all the supporting stuff myself.

Thanks, Pete KA TZK Colorado

Mark,
It really isn't that the earth around a ground rod must
be moist, but that the ground rod should be long enough to
get into the local water-table to be affective. In a base-
ment, depending on where you are, the problem would be to
keep the moisture ~out~ of the basement.

Well, I got the ATAS-100 and it worked for about two days then it
stopped tuning. I took it back and exchanged it for two Isotron
combinations. 80/40 meter and 20/15/10 meter. They are
mounted on two 5 foot masts supported by rooftop type tripods.
Currently standing in my living room. Works well with a tuner.
Sure glad I got that MFJ-259 analyzer to set them up with.
I hope to transfer them to my second floor balcony when the
weather warms up a bit. Live and learn. 73 Gary

I was thinking the same thing you were thinking. Jerry (how to get that antenna onto the top of a pine tree). Of course, since the "tree" is only eight foot tall, he has a couple of options - renting a bucket truck or purchasing the spiked boots used by telephone pole linesmen. The bucket truck is much safer at those heights, don't you think? ;-)

I have used an attache-case, 160m, 50 watt, home-brew transceiver
on several occasions in hotel rooms.

Ask for a room at the rear of the hotel on the top floor (because
you like the view).

Throw a 22 awg, stranded, brown plastic covered wire out of the
window. Let it dangle down the wall as far as the garbage bins. As
long as possible up to 120 feet.

A tuner is essential. 350pF receiving-type variable plus
multi-tapped coil wound on toilet paper tube. Plus perhaps another
350pF varaiable or a few fixed values of mica capacitor.

For the ground connection take a big aligator clip and clip on to
the copper cold water pipe to the hand-wash basin. Or clip on to
the hot pipe feeding the central heating radiator. Better still -
both together.

If you don't want to risk disturbing the neighbors in the next
bedroom, take a morse key and a pair of headphones.

Set up the rig in your own bedroom at home and prepare a check list
of things to take several days before leaving home. Don't forget to
take an adapter or adapters for all types of power sockets you are
like to be confronted with. Screw driver. Side cutters. Odds and
ends of wire with crock clips. Log book. Licence. Ball point pen.
Wander plugs and sockets. Soldering iron and resin-filled solder.

Don't leave the iron on the bed clothes while you are waiting for
it to warm up.

Another alternative is to use the 20 some odd ft length of galvanized top rails for chain link fencing. Two or more can be snug fitted together and can be guyed at the joints. These are fairly stout as well as inexpensive.

<snip>

I like your inverted V idea. Another one I like the sound of is the St. Louis Pocket Vertical, a loaded vertical made from sections of kite rod. This is a compact version of the St. Louis Vertical; I am still trying to locate the QRPp construction article for it. Yet another antenna I am experimenting with is a continuously loaded vertical-- according to Antenna Handbook, wind 0.5-lambda of wire on an insulating support 0.05-lambda long, add a corona disk, radials, and L-match.

I've found various sources for telescoping masts. One can of course buy these meant for antennas but they are usually too big for backpacking. There are telescoping fishing poles and telescoping wind-sock supports. Both are lightweight and tall, but don't collapse small enough for my taste (4ft). What I'm considering now is using fiberglass kite tubing (www.intothewind.com), make some short (2.5ft) sections and connect them with ferrules to get desired length.

Where I go backpacking there are plenty of trees, but I am wanting to run QRP from the beach this spring, so I'm also looking for compact, quick and easy setup and no natural support structures.

Years ago I had a chance to operate a 30 mt (or more) high double cone antenna and I compared it with a Windom for 160 mt mounted on two poles 25 mt high.
This happened two days before a contest and I decided to use the Windom, since signals was 2 S greather than the 'monster'. (I don't remember if it was on all the bands).
Just before the contest started I checked again the two antennas and... surprise: this time the monster gave 2 S more than the Windom on the same signal!!
After more checks with the same results and few hours thinking about the miracle, I realized that the days before it had rained a lot!!
Sure a wet ground is a great help.
I can't say much about salt; only that it should increase the conductivity of water, thus should helps. But what about the life of radials in a salt environment?
And wat about grass and plants, as should ask Greenpeace?!

I would suggest a Z-match tuner for an application like this. There
are a couple of inexpensive kits (QRP-only) you might consider:

Emtech ZM-1 (http://emtech.steadynet.com/zmdesc.htm)

NorCal BLT (http://www.fix.net/~jparker/norcal/kits/kits.htm)

> There's something here that few would pick up on. The velocity of the
> wave in free space and the velocity of the wave in a media different
> from free space are accountable by the media that is different.
> This is simply Snell's Law.

refraction, (r�-fr�k�shen) the deflection of a wave on passing *obliquely*
from one transparent medium into a second medium in which its speed is
different, as the passage of a light ray from air into glass.
The index of refraction of a transparent medium is equal to the ratio of the
speed of light in a vacuum to the speed of light in the medium.

Snell's law states that the ratio of the sine of the angle i of incidence
(angle between the incident ray and the normal, or line perpendicular to the
boundary between the two mediums at the point of refraction) to the sine of
the angle r of refraction (angle between the refracted ray and the normal)
is equal to the ratio of the refracting medium's index of refraction nr to
the original medium's index of refraction ni.

So if it is as simple as that why is the polar diagram of a half wave Dipole
different to the polar diagram of a whole wavelength antenna and so on?
The polar diagram of a simple dipole has the centre normal to the dipole, if
Snell's Law has a strong effect might one not expect two lobes not normal to
the dipole?

> However, you slide into the speed of the current in the media and try
> to correlate it to the speed of the wave in free space.

Snell's Law deals with the wave along the direction of travel of the wave.
The induced current is normal to the direction of travel of the Magnetic
flux. Or wher the magnetic flux comes from a direction not normal to the
wire then a vector proporition of current is induced. Untill the wave
arrives along the axis of the dipole and no current is induced in the wire.

>Two very different beasts. Let's simply stick with one media when we
examine
> the speed of the wave and the speed of the current.

OK the Speed of the wave in air is C the velocity of light,
approximately 3 x 10^8 m/s
The speed of the current in the medium (Cu) is 75 mm per nanosecond.
aprox 7.6 x 10^7
Or one tenth of the velocity of the wave in air.
And yet we cut the wire to a fraction of the wavelength in air.
How so?

> If, perchance, the speed of the current exceeds the speed of the wave

Yet the speed of the electron in the tube was too slow for UHF,
thus the Klystron was born. Of course you are familiar with bunching and
velocity modulation of the electron stream.

> Now the really remarkable fact about this last near light speed
> current phenomenon in a tube is that it conforms in every sense to

> Resistance is as real as a chunk of carbon and produces the heat to
> prove it.

In soft tubes may be.
Though I must admit to seeing a few red anodes in my time.

Ra = dVa / dIa
A rule of thmb the Plate resistance is aproximately inversly proportional to
the cube root of the plate current.
Thus when the tube is off Ia = 0; Ra approaches infinity.
Which is what we find in practice.

> Back when Hams built their own rigs, you can be sure they
> were aware of their plate "dissipation" limit for ANY particular tube
> they designed around.

Yes indeed and class C became very popular.
Clever designers arranged Rl and Ra such the the majority of the power was
not in the tube, but in the Tank. ;)

> Some may confuse the heat shedding of the plate
> as simply the process of being illuminated by the filament.

Ha, hi, I've never heard that one before. :)

>That is,
> a coffee pot gets hot because of the stove's burner - heat transfer by

But what has this to do with the difference of velocity of the wave in free
space and the velocity of the current in the medium.

On this same topic, I have had some thoughts of trying to install a vertical just above some of my trees by pushing a segmented pole up the center, assembling the pole as it goes up.

If I could figure out how to fasten the pole to the tree trunk without climbing up there, I think I would give it a try. I have looked up the trunks of several of them, hoping to find one with branches oriented in a way that would naturally "enclose" the pole, but haven't found a candidate yet.

Sure would be nice to have the tree doing all the guying work for me, with the pole just supporting the weight of the antenna.

Of course you do.

> Most people understand the end result.
> Describing the process is where problems usually arise. My
> comments were directed at your statement "if there is no dissipation there
> is no propagation".

The only thing that the operator can know of space is what he can see going
on on his instruments at the input to the antenna feed system. When it's
cold and dark outside the Ham cosseted in his candle lit shack
, unwilling to peer out into the frost covered world could have his AE
snipped from his feeder and a matched resistance substituted. His
instruments would tell him no more of what was going on outside in the dark
dark night.
Just how many measurements of a electromagnetic wave in full flight have
been made? Most of what we discuss is purely theoretical, and we trust it to
be correct in so much that our theory permits us to make certain limited
predictions about the behaviour of out apperatus. Unlike circuit theory
where imperical experiments are easily conducted, substitutions, variations
and measurements permit a measure of confirmation of our hypothesises. But
waves in freespace are not quite so easy.

> Dissipation of energy in the form of heat is not a
> requirement for the propagation of EM energy.

Of course not.

> It may however, be part of the propagation process.

It is the propagation process, just that the mass is almost zero at most
points, so the wave has to travel a very long way before it becomes
completely dissipated.
(I have a picture of a resistor exploded so that it's molecules distribute
themselves evenly thoroughout the universe. Will those molecules respond to
that E-M wave in the same way as they did when they formed a part of the
original resistor?)

Which raises the question;
does a 40 Watt wave travel twice as far as a 10 Watt wave?

>The distribution of energy in space as it travels
> away from a source is not a heat dissipation issue as your statement might
> lead some to believe.

Ah! the 'leading' is partly the Imp within me, but the root cause is wanting
to stimulate people to think.

3579. Disphased source under Nec4Win

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-21 22:06:55 UTC
From: Jean Schwoerer <jschwoer@ens.insa-rennes.fr>
Message-ID: <Pine.LNX.4.21.0102212256550.12530-100000@stang.ens.insa-rennes.fr>
Source record: 169853

Hi folks

I'm trying to simulate an antenna formed by two 90ï¿½ crossed dipoles and disphased of 90ï¿½ under Nec4Win

My problem is to create the two disphased sources. I don't know how to do this.

If someone has an idea or somme docs....

Thanks for your help

Something like that.

Regarding the safety aspect of me climbing to those dizzy heights, I think I'll saw the trunk off low down, install a hinge, and lower the tree to a safe working height whenever I need to fiddle with the aerial. ;)

> Boy you're in for a long wait.

Maybe I could insert a section or two of pole above the hinge, painted brown of course so that the neighbours will think the tree just grew a little overnight.

> Glad to see you using a Discone, as an acquisition aid they are ideal.
> For radio mapping the site probably the quickest way.

This is my backup tx aerial, mainly used for rx of local airband. My main aerial is a Diamond V2000 on a 16 foot pole. Yes I know, that's not the highest aerial in the world either, but I can't get away with much higher on the bungalow before domestic planning permission is withdrawn.

Cheers,

Mark.

<:?) duh! Stanley, another fine mess you got me into.

If you're going to the funeral look out for Quincy.
BTW it ain't how far you fall, but how hard you land that finishes you off.
Some people have fallen thousands of feet and survived whilst others have
merely tripped and kicked the bucket as a result.

As far as the original question, leave the pole tied to the fence and plant
an ivy plant at the foot.

I tried to order this item a couple of times(33 foot fiberglass mast) and they do not have it. But they will put you on a waiting list for when they do have it, but who wants to do that? I guess I will get it from the German ham that has them at Dayton each year. Ideal portable, field day mast.

>

Au contraire, OM...

Quoting from my 14AVQ Installation & Operating Instructions:

"
NOTE

If the terminals of the input connector are checked with an ohmeter they
will show a direct short. THIS IS NORMAL! The matching coil in the antanna
base puts the entire system at DC ground but presents a perfect 52 ohm
impedance to RF energy. "

Emphasis in original. Original in italics.

I bought mine new in 1970...cost $39.95, IIRC. It's pretty beat up now but
it still works, altho I don't use it any more.

Hope this helps...

I need to make a balun using a 1/2-wave section of coax cable. I must take into consideration the velocity factory of the cable when measuring it. I know it is probably simple, but it escapes me at the moment. What is the equation for this?

Thanks.

>the dipole?
>
There are mechanistic descriptions of how this happens (the difference
between the two structures and their lobe patterns); but they are
basically the same discussion from two points of view. The hinge to
turn this on is that for Snell's Law to work meaningfully, the scale
of the lens (or element) has to be large in relation to the
wavelength. With antenna elements, we are simply more used to
viewing small, small lenses for antennas and large, large lenses for

Optics. If you look at an Optical lens that is scaled similar with a very small geometry, then you would encounter the same issues we struggle with in antennas. Contrariwise, if you worked with an antenna that is very large in relation to wavelength (and with more than just a driven element), then you would observe classic Optical lobe patterns.

Snell's Law works equally effectively or ineffectively based upon the scale of the geometry (for which we often limit our discussions' geometries typically below one wavelength).

The speed of the current of electrons in Cu is at least 7 orders of magnitude slower. The speed of the current's effects is what you are describing.

>Or one tenth of the velocity of the wave in air.
>And yet we cut the wire to a fraction of the wavelength in air.
>How so?

This is to satisfy matching criteria more than launch characteristics. A practical small (or less than one wavelength geometry) element for either Optics or RF will present the same launch characteristics of a lambertian distribution. Do not confuse the practical element with a point source however.

Yes, very familiar. But it still serves as an obvious example of near
light speed current, even if it is too slow for the scale of geometry
being imposed as a practical necessity.

>space and the velocity of the current in the medium.

Hi Gary,

I would speculate that your question is not so much about tubes (my
focus for this discussion and the subject of this thread) but rather
with an antenna and the open space it is found in. This actually

changes nothing but the physical scale of the discussion. There is one point that can be fraught with problems: there is no current of electrons flowing in free space in the same manner as between the cathode and the anode of our tube. The current of free space is "induced" too. Being "induced," the effects are transmitted at a speed as a function of the media's density (a denser media will propagate either light or RF slower); however, the electrons in this induced current that move as a consequence of the initial current in the tube will never move as far, nor as fast as within that same tube.

The frequent homily heard here is that radiation is a product of the acceleration of charge. This only happens at the source, and everywhere else an induced current moves the effect as quickly (in relation to the media it is moving in), but not the charges (electrons). This warn aphorism has been tossed around so much, I am surprised that the same one's who use this crutch don't acknowledge that the deceleration of charge is a dissipative (their words) resistance already found in the source.

Hello,

I wanted to know if 2 Omni antennas arecapable of being used as a point to point system?

example:
Building A - Omni antenna

Building B - Omni antenna

Or, does one of the antennas need to be of the directional type?

Thank you in advance
Kell Jemison

VF depends on the dielectic. It's 0.66 for RG8, RG58, RG213, RG214
RG174, and RG316. It's 0.84 for 9913, and RG8X. 0.85 for LM400.

Source record: 169771

The velocity factor is 1/sqrt(K) where K is the effective dielectric constant of the dielectric containing the field. In coax, the field is entirely within the dielectric, so K is the dielectric constant of the insulating material between the conductors. This works out to be a velocity factor of 0.66 for solid polyethylene and 0.69 for PTFE Teflon insulated cables. I've measured a number of foamed dielectric cables and have found them to vary a great deal. Apparently the manufacturers don't have very good control over how what percentage of air the mix has. (And, since they do seem to control the conductor diameters pretty well, this means that the Z0 varies quite a bit.) I measure the VF of a foamed cable if it's really important. I consider the manufacturer's specification for foamed dielectric cable only as a guideline, and expect to do some cut and try if that's all I've got to go by.

You'll need to tell us what you mean by "best". Best price, easiest
assembly, easiest tuning, best construction, highest gain, lowest
SWR, nicest looking, etc.

I think an elevated ground plane has a place, but not on 160m. Or at least not unless you want to mount at a minimum of 125 ft in the air. And at that height even though 4 radials will do a good job, you really need 8-10 to equal the 120 on the ground. Add to that the 125 ft radiator if full size, and you are looking at a 250 ft high structure which likely won't be too much better than the antenna on the ground with 60-120 radials. I don't think it's worth it in most cases. I'd probably rather run try 250 ft structure as a 1/2 wl with 1/2 wl radials on the ground ala BC. But the higher bands, it's not too much trouble to run a ground plane. You can multi band to an extent. I ran my 40 gp on 17m as a 5/8, and it also did fairly decent on 15m even with the fairly high angles. But I had to run a 24v relay to switch bands by bypassing the coil for 17m when used on 40m. But if money or height were no object for one band, I'd probably rather have a GP at 1/2 wl with 4 radials, than a ground mount with 120 radials. I think the added benefit of being clear of the surroundings helps a bit. But of course on 160m, this is a appx 375 ft structure. Won't be happening here any time soon. Heck, even on 40m, you need an elevated GP 35 ft in the air to get by with 4 radials and have decent performance. I know that from trying it here. It did not do near as well when lowered to the 15-20 ft level. How people think they can use less than that height on 160m and do well is a mystery to me. I guess they think they do well, because they have never tried the many radials on the ground to compare to. Or they have never tried the elelvated antenna at a decent height for them to work properly. MK

You mean the VF problem, or the 1/2 wave of coax problem? Tne formula
for the 1/2 wave of coax is
492 x VF / freq .MK

> receiver sensitivity.

Assume identical systems, in fact the same systems,
but with the wick turned up a bit on the transmitter.

> If you can't receive the 10 watt wave, is it really even there?

That is threshold, the thing is, can you move your receiver twice the
distance away if you use 4 times the power?

Now prove it, assuming an Rx with a noise temperature of 12°K, no
modulation?

Remember that those deep deep space spacecraft only have 10 Watt
transmitters on board.
What is the limit of their useful range, (assume unmodulated)?
note: space loss to 16,000 km at 2 Ghz = 183 dB

What is the duration of a mission [time to reach threshold]?
Assume a vector velocity away from the Earth of 29,250 MPH
[13,000 m/s]

Assume a useful 3 dB signal to noise ratio for data transmission at 8Hz,
how much shorter in time and distance is the mission?
Show calculations.

> > >The distribution of energy in space as it travels

I hope that we can enjoy it together.
You guys are fine examples of remaining cool and calm in debate and not
resorting to personal insults, (the sure sign that the argument is lost).
It is nice to keep the conversation as light though serious as possible in a
hobby group like this. Hopefully remembering the meaning of the word hobby:

hob�by (h�b��) noun
plural hob�bies
An activity or interest pursued outside one's regular occupation
and engaged in primarily for pleasure.

[Middle English hobi, hobyn, small horse,
hobby horse, perhaps from Hobin, Hobby, nickname for Robert.]
� hob�by�ist noun

And ensuring that the primary purpose of 'pleasure' is served first and at
all times.
Of course my remarks are not aimed at you specifically,
please forgive me for using your post as a billboard.

Reg:

Thanks for the detailed explanation of the progress of the thread and Tom's and your positions. I had not been following as closely as I should have. You did a good job of summarizing the thread.

After due consideration, heere's my comments on your controversy over Q with Tom...

When it comes to measuring high values of Q, the most applicable "old wives wisdom" applicable is the old cliche, "in theory, theory and practice are the same, in practice they are different."

I do understand that the "accuracy" of a Q measurement or calculation depends critically upon stray or secondary parameters which are often difficult to measure and that the higher the value of Q, the more inaccurate the calculation or measurement must be.

The "perfect" Q is infinite, or at least very very large compared to our experience, but the closer one approaches the infinite the more difficult it becomes to measure or calculate, and the higher the inaccuracies in its' determination, both relative (%) and absolute!

Q suffers from that affliction common to many "difficult to determine quantities", which is that it can only really be determined as the difference between two large numbers which are very close in value. Generally determining such a difference is a thing you don't want to be doing!

Most laboratory measurements of Q are made by simple instruments by making use of the "approximate" formula Q = f0/(f2 - f1) where fo is the resonant frequency and f1 and f2 are the two "3dB down" frequencies on either side of a very sharp resonant peak.

Now if Q is very large, say up to 10,000 or more and f0 is in the MHz, then f1 and f2 are two very large numbers quite close together, and their numerical difference will dimish in signifigance so as to frustrate the most persistent of metrologists! Heh, heh.

In cases of very high Q's even 10 digit calculators won't be able to determine the difference between f1 and f2, even if f1 and f2 could be individually measured to the required accuracy.

Because of the nature of Q, i.e. perfection is immeasurable [infinite], and as Q approaches its' perfection, the accuracy with which one can know the precise value of Q decreases. Frustating! This is because it is essentially a strong function [reciprocal] of the tiny difference between

two very large numbers of approximately equal value. Thus all discussions of Q are destined for difficulties and controversy.

And so... for satisfactory resolution of these controversies, the protagonists, [Tom and Reg?] require the most candid and detailed sharing of both laboratory results and mathematical models.

To make progress, one must push forward into the details of both the lab measurements and their error analysis and with the mathematical models used for calculation.

I do understand that, because of these facts, low values of Q are easy to calculate and measure, in terms of their relative accuracy.

And that [extremely] high values of Q are extremely difficult to measure accurately.

For instance the Q of a quartz crystal [Which is the equivalent of a simple LC series tank circuit.] can often exceed a value of 25,000 - 100,000 or more! I challenge anyone here to produce for me a standard "off the shelf" Q meter made by any manufacturer that will even give a satisfactory "indication" of, let alone an accurate value for the Q of any quarz crystal.

Does anyone reading this thread know who makes Q meters for measuring the Q of quartz crystals? A very narrow field of instrument sales indeed.

And so, I agree that measuring, and indeed calculating, the values of Q, especially for high values, is fraught with difficulties and not for the faint of heart.

Getting agreement between measurement and calculation for high Q values is extremely difficult and depends critically upon a full understanding of all the things, both practical laboratory measureable things as well as mathematical model things, involved in the measurements and calculations. And as we know, most of those things are "secondary" or "stray", i.e. they are things like interwinding capacitances for example, that do not appear on anybody's schematic diagram. They are things which often no one knows are there until there is a disagreement between theory and practice. And so getting agreement on them is difficult.

Only when we get disagreement between theory [mathematical model] and practice [measurements] can we refine and perfect both!

And with Q, as with life, we are ultimately destined to "fail" for as we push forward to ever higher values of Q trying to reconcile theory and practice we will continue to find ever larger areas of disagreement. In life as we push forward we face death. That's exactly the end result for the final successful determination of very high Q's. We will all be dead by the time we can successfully measure a Q of 100 million! Ultimately the difference between theory and practice will itself become the difference between two very nearly equal large numbers... and once we reach that lofty level of disagreement, well...

Reg says the Q is infinite [Oops his computer registers just overflowed!]
and Tom agrees that he also measures an infinite value on his lab Q meter,
who among us will dare...

to punch those two infinities into their lowly desk calculator and press the
difference key (that's the "-") to find the difference between those two
infinities and determine the winner... Tom or Reg....

In theory, theory and practice are the same, in practice they are
different...

We are all presented with an opportunitiy to learn new things here... if
only theory (Reg) and practice (Tom) would collaborate on this thread, if
only they would share, and be more candid and open about their mathematical
models and their laboratory practice.

If you both hold your cards to the vest then no one will win! We all have
something to learn here. Cooperate, "just do it!"

Thoughts, comments?

I have a real nice HF6V vertical antenna ready to put up on my town house rood problem is that I can not run all the ground radials in 360 degrees pattern and I do not have like 33 ft on some sides for the 40meter ground I have like half a "Pie " shape to work with what do I do?? I really want to put the antenna up and have it work good.. I do see that there is a CPK Countpoise kit but not shure if I want to buy that and install it... how about the roof radial kit from Butternut is it work buying and waht do I do when I can not put some radials out using only half of my roof any help on this please...

Hi Richard,
I would Checkout Butternut , you will most likey get all kinds of
conflicting advise . But in my book the Butternut is the best all round
vertical on the market today.
Web page at
http://www.bencher.com/ant_select.html
hope this is of some help in your search .

The attenuation is rising, but the voltage displayed is falling.

Are not the losses in shunt with the line?
The dielectric losses generally being more signicant than the conduction los
ses in distributed series with the line.

> Reg is correct in saying that you could measure the Z0 of an infinitely
> long line with an ohmmeter.

Only if you are very quick. ;)
Whatever became or Evershed and Vignoles Megger bridges?

>But only if the line has absolutely zero loss.

Just like a good quality capacitor

>For ordinary cable, I imagine this would
> happen much faster than the meter could respond, but you'd have to have
> an impossibly long piece of it to do a test.

And what type of Ohm Meter would you use?
a Multimeter
a Whetstone Bridge
a Megger

Each of these might be expected to have different internal resistance and
some would act as a voltage source and some a current source.

Mostly I am looking at performance based things. I don't want to buy
something cheap and it turn out bad. Looking for the best overall
performance for 400 dollars or less. I have heard a lot about GAP Antennas
but just wondering how good they are. I have seen the Butternut type of
antenna but looking for the best performer at a fair price. Hope this clears
up my question somewhat better. Construction and tuning is realy important
too. Thanks.

Zo = SQRT(L/C)

What meaning does L have at DC once the steady state is reached
di/dt becomes zero therfore Ldi/dt becomes Zero and the voltage drop across
the series inductance is only that due to the resistance of the wire, for Cu
160 uOhm per metre.
Of course for an infinitely long line the nth minus one distributed
capacitor is not going to have a lot of voltage difference across the line
left to charge it.
So this wouldn't be a lossless line.
We would need to use a superconductor to realise such an animal.

> The inductance allows current to rise but inhibits it. Capacitance
> readily accepts current but inhibits voltage rise.The long line with
> distributed iductance and capacitance does not appear as either an
> inductance or a capacitance. It appears as a resistance. Not the kind
> that eats energy, only the volts over amps kind.

Volts over amps provided that both last for long enough to be measured is
surely energy eating.
What you are really saying is that the time span over which you wish to make
your measurement is to be limited.
If you blink whilst making this Ohm meter measurement you'll miss it.

Oh! I forgot it's an infinite line we'll never know if it is open, short or
matched.
We just keep supplying EMF and the line keeps on eating current.
I think the other end of this line must be dangling into a black hole and
all the electrons are being sucked in never to return.

> There is no charge-up exponential decrease in current into the infinite

It depends if you are considering the line a a point z "along the wave path"
in which case you are considering an alternating Voltage, or if you are
considering an instant in time in which case we will see a voltage varying
along the z axis gradually changing polarity.
There is no gap in the excitation; it is a smooth process in general
following a sine law.

Hi Richard,

I too had a Butternut vertical ground mounted. I got great results with it. If you have a melal type fence around the yard such as hurricane type fence, mount it on one of the post as the fence helped give it counterpoise. My buddy did the same after seeing the results of mine and he noticed a big difference and even worked dx with the big boys without any amp. I sold mine but am thinking about another one and taking down all the tower and antennas to go low profile.
Good luck and 73's.

de Huey(n5dvi)

Lots of hams buy something expensive and it turns out bad. The
necessary ground plane for a vertical is more effort and expense
than a $20 dipole which may outperform it. Why not try the $20
dipole first?

me 2, we've gone all around the houses and had a lot of fun, now lets get
down to the fun-de-mentals of propogation.

> but rather
> with an antenna and the open space it is found in. This actually
> changes nothing but the physical scale of the discussion.

Agreed and Snell's law didn't really help a lot here, as the physics of Ham
antenna are of the order one wavelength or less

>There is one
> point that can be fraught with problems: there is no current of
> electrons flowing in free space in the same manner as between the
> cathode and the anode of our tube. The current of free space is
> "induced" too.

Quite a difficult thing to get to grips with.
For instance as an Imp I travel on a magic sley on the front of a wave
traveling out from a virtual point source. The flux expands as the surface
of a sphere out into space at PI x C
Iin other words a little greater than three time the velocity of light.
When the wave gets some good distance away from the source that flux is
spreading instanteneously throughout space. (Magnetic or Electric applies
equally)

So what is the real nature of this flux?

What is the nature of the flux (gravity) that ties the motions of the
spheres so closely together.
How can the motion of the almost invisible planet Jupiter so affect the
orbit of the Moon?

How is it that the influence travels so rapidly across such vast distance.

> Being "induced," the effects are transmitted at a
> speed as a function of the media's density (a denser media will

Perhaps a better way to visualise this is to consider the Cathode Ray tube;
where the effects of the electrons and their kinetic energy may be easily
demonstrated.

> The frequent homily heard here is that radiation is a product of the

> that the deceleration of charge is a dissipative (their words)
> resistance already found in the source.

And what happens as the electrons plough into the phospher of a CRT?
Energy is dissipated, but resistance can not be demonstrated.
The answer has been sitting in front of us un-noticed for years.

You really would benefit if you could get a bit more height to bring the
radiation angle down a bit. Higher the better, bit like standing on a beer
crate so that you can see over the top of a high wall.

Can you hear Barkway from your QTH?

Gary Peach wrote:
"What is the limit of their useful range (assume unmodulated)? note: space loss to 16,000km at 2GHz=183dB.

The signal is periodic. Processing to distinguish this periodicity may be improved making a weaker signal detectable. How much can sifting the signal from its background be improved?

Whatever the noise temperature of a receiver, is it the ultimate?

Do the antennas used have the most gain you can get?

Can more transmitter be used? Can it be saved up for a big pulse?

Gary asked previously if 4x the power would send the signal 2x the distance. In general, the answer is yes when all else is equal. Every time the distance from a signal source out there in space doubles its level drops by 6 db. If space loss is 183 db at 10,000 miles, at 20,000 miles the loss is 189 db.

The gain of a dish is proportional to its diameter in wavelengths squared. How about a larger dish?

A highly directional antenna needs to be located so it isn`t aimed at a big noise source. Point it at the sun`s 6000 degrees K surface and receive 8.28x10 to the minus 14th watts or -101 dBm. This happens to satellite earth stations in the spring and fall for a short time each year. Your cable TV company announces what is happening, I suppose.

The greater the distance between transmitter and receiver, the greater doubling the distance increments the distance. What`s the limit? Is there any limit?

Best regards, Richard Harrison, KB5WZI

Peter, K1PO wrote:
"Now why would you want to mess with a silly term like "dissipationless resistance"?

Surge resistance is a good term for a transmission line because it is descriptive of the dissipationless resistance exhibited by the line.

Surge resistance doesn`t describe the resistance of an antenna`s radiation load because the energy fed the antenna is being projected forever along the antenna`s length.

Surge resistance doesn`t describe the average impedance caused by an open switch during a portion of an amplifier`s conduction cycle.

The generic term "dissipationless resistance" fits them all and helps understanding via the commonality of the in-phase voltage to current ratio which has no heat conversion.

Best regards, Richard Harrison, KB5WZI

Good, I hoped you didn't take my response as a smart-a** one. Like the
others who responded, I'd recommend the Butternut HF6V (or 9V if you
want the WARC bands and 6M). I have one, roof mounted with the roof
mount kit (includes tripod and radials). Excellent construction, easy
to assemble (if you follow the instructions), but I have to be honest:
tuning it can be a sub-hobby in itself. Once you have it tuned though
it's a great performer.

As a side note, one of my friends has a Gap Titan and he's very happy
with it.

Hi Peter,

You have succumbed to the old wive's tale of the Q meter posed in this thread (off the shelf instrumentation indeed!). The Q Meters that have passed over my calibration bench had incredible Q's by virtue of being cavity resonators. I doubt if this specie qualifies as what this board would consider as "off the shelf." For one it dismisses the artificial premises here as absurd.

Your question above can resolve itself in simply exciting that crystal and measuring its frequency spectrum. This is already responded to by Gary in the classic determination of Q. You pine away about 10 place measurements, and yet frequency can be measured out many more places without too much effort (but certainly at a lot of expense). Given that the frequency standard of the Cesium Beam is absolute, any measurement against it will result in a beat frequency that is easily measured. I am not going to hedge my bet with the native frequency of the Beam against a crystal of the same frequency, that would be a slam dunk (if you could in fact find such a crystal).

However this focuses on the obvious solution at the expense of a repertoire of other methods that can achieve the same end. I assure you that metrologists are not so easily discouraged at technical challenges. This, however, hardly rises to the merit of "technical challenge."

Industry and the marketplace care not a whit about super Q devices. Hence the quality of "off the shelf" instrumentation is limited to their less demanding needs. Science and Engineering is not limited to the marketplace for solutions. The tenor of the question of how to calibrate a Q Meter reveals a basic ignorance of measurement, or is offered as a troll.

Cecil,

Still theorizing (and negotiating with my wife<g>) about my first HF antenna. I am considering the possibilities of hybridizing your No-Tune dipole and your rotatable dipole into a helically wound rotatable dipole. Ideally I would wind heavy gauge copper (#10 or #8 or #6) on a form like a 4" PVC pipe and then remove the pipe and tune it with your ladder line tuner. What I am attempting to accomplish is having as much bandwidth as possible with an antenna that has somewhat stylish appearance I can sell to my wife. I am envisioning two self supporting coils protruding from opposite sides of a mast.

Can I use a 4" diameter helically wound antenna without having an insulating core and is there a limitation about how close the wraps can be to each other? Do you see any other gotchas in my thinking?

TIA

Hey guys,
I'm re-designing my mobile setup and need some advice. I have 1 antenna that is a Larsen Kulrod for 440 MHz. It is an NMO with the magnet mount. I am thinking of using something other than an NMO. I also want to move away from a mag-mount and go to a permanently mounted antenna. I have seen another connector that is a direct "screw-on" type connector (Not BNC,SMA, or NMO), it seemed like it would be more durable than the small contact in the NMO because it was just a stub with threads. Any suggestions will be appreciated. TIA

Use the helical coil form as the insulating core. Gamma/Delta feeding
an all-band antenna gets very tricky. Another thing to worry about is
self resonance in the helical antenna. I don't know how to predict
the self-resonant frequency of a helical. Does anybody else?

Source record: 169803

Hi Richard,

Well over my years of hamming Ive owned 3. Hustler, Cushcraft and Butternut HF6V. I consider the Butternut the absolute best of the models. The Hustler I had when I first started in Calif. I did ok, but was damaged when I shipped it to spain. So I ordered the Cushcraft on recommendation by the mags. It did ok, but while I was there a friend of mine bought the Butternut and since we lived about a mile from each other we did comparisions over a year. He consistantly KILLED me in pileups (as verts go) so when I got to Maine I used my vert about a year more then sold it at a hamfest and ordered the Butternut. I have beams now but the butter nut served me many a year.

Its a great antenna if you follow the instructions it works the first time up. Get a the roof mount kit, well worth it.

I hear the HF9V is just as good.

Good luck
Rick KF7QZ

> Thanks.

Because the velocity factor varies from run to run, simply plugging in a manufacturer's number may not be sufficient. If you have an antenna analyzer you can use it to determine the correct length. But to answer your question, calculate a free space half wave an multiply by the VF.

Try the ARRL web sites Technical Information Service page.

http://http://www.arrl.org/tis/tismenu.html

Then select "Antenna Projects" and then "Trapped Antennas".

There are 4 articles, from QST, on trap type antennas. What
you are looking for may be in there. The articles are in
PDF format.

Well, it didn't have a label on it reading "Q Meter", but I used an
H-P 3577 network analyzer and software I wrote to measure 1000s of
quartz crystals and calculate their motional parameters. From this, Q
is easily determined.

Saunders & Associates makes crystal measuring equipment to do this on
the fly during crystal processing. http://www.saunders-assoc.com/

It's not at all difficult to resolve a 1.4 kHz difference between two frequencies at 14 MHz. Your receiver does it without strain, as does even a very inexpensive frequency counter. In any case, high accuracy isn't required, just moderate resolution.

Somewhere around 8-10 years ago Wes Hayward, W7ZOI, wrote some excellent articles on designing crystal ladder filters. I believe one was in QST and one in QEX. Some filters require selecting crystals, and in the article was a simple circuit for doing that, which anyone could build at home. I'm quite sure it could be used to get the crystal Q with reasonable accuracy. Perhaps someone with easy access to the article can confirm that.

Is transresistance (amplifier output voltage divided by input current) dissipationless? How about the dynamic resistance of a diode (the reciprocal of the slope of the I-V curve)? The R0 of a lossless cable is obviously "dissipationless". How about the resistive part of the Z0 of a lossy cable or other transmission medium? It looks like we've got to stuff all resistances into two pigeonholes, "dissipative" and "dissipationless". So please help me out in deciding which hole to put these in.

3642. How to match a Helix Antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-22 19:16:49 UTC
From: Helmut Wabnig <hwabnig@aon.at>
Message-ID: <fbma9tc4nr9e6ojh32e02b0lqv6bdllaj8@4ax.com>
Source record: 169815

Dear readers,
am trying to solve a mystery.

Have surfed at about 20 WWW pages with description,
about helix antennas, but all, with no exception, avoid strictly to
explain the matching section. There are drawings without explanations,
there are photos with hide just the critical details.

Yes, there are references to the ARRL Antenna handbook.
Yes, I bought the ARRL Antenna Handbook 19th edition.

To anticipate the result:
The ARRL chapter about the Helix is complete BULLSHIT.

The helix is very critical to match, this I know from my experiments.
At higher frequencies, say 2450 MHz, the geometrical dimensions
must be within millimeters of tolerance. To match the 140 Ohms
to the 50 Ohm cable, several possibilities I found:

1.)Quarter wavelenght transformer, about 84 Ohms.
Helix ends 0.13 * lambda above reflector plate.
Theoretically easy to calculate the dimensions, but practically
difficult to make, because already the N connector
is of a considerable size compared to the geometrical dimensions.
Impossible to adjust correctly without measuring equipment.
ARRL shows an illustration with a "feed wire" running
from the helix end to the N connector page 19-23.
Thats no match, listen, its bullshit.

2.)Bending the lowest winding towards the reflector plate.
Contradictory to the 0.13 * lamda formula.
No theoretical insight how that would fit.

3.)Soldering a strip to the last quarter turn. ARRL does give
a picture, without the information how to dimension the strip.
No explanation given, just bend the wire, until you loose patience.

4.) Not given by ARRL: make a microwave impedance
transformer by cutting a metal sheet to the form of an
elongated triangle, wide end soldered to N connector,
tip of the triangle soldered to helix end opposite of N.
For this I would like to find the dimensions calculations.

Instead of giving detailed information about the technical
aspects of that antenna, the author goes astray and blusters
about how to make wood weather proof.
Would you use wetted wood in a microwave antenna?

Good luck then :-)

Its beyond my comprehension why the ARRL author insists
on matching to 52 Ohm cable. Am not quite sure about that,
but as I recall, my cable catalogue lists only 50 Ohm cables.

Dear reader, what we should go for is not a cooking recipe
"thats how I do things", we need some theoretical
insights before we start cutting and soldering
sheet metal. Hints to literature, www, or paper,
exact broadband and narrowband helix matching welcome.

Thanks for reading,
W.
OE8UWW

Hi Roy,

This is a common failure mechanism of LEDs when you observe their
requirements for heat dissipation. The forward voltage times the
forward current is indeed rendered into destructive heat.

Early Blue LED designs having a very high forward voltage (on the
order of 3 Volts) could not sustain the industry standard of 20 mA
without catastrophic destruction.

There will eventually be a point when the wave has insufficient energy to make any difference to the input condition of the receiver, the wave will be spent.
Please do not complicate the issue by using FFT etc.
This is a question for Hams with elementary mathematics.

> Whatever the noise temperature of a receiver, is it the ultimate?

As far as we know no, but at this stage consideration of hitech system enhance ments such as MMT will not advance this discussion of propogation. I am trying to get to grips with the simple mechanics of propgation of a signal and the limiting physical factor.

> Do the antennas used have the most gain you can get?

Spacecraft 30 dB, ground Rx dish 60 dB, Ts 12K

> Can more transmitter be used? Can it be saved up for a big pulse?

That is not the question.
The transmitter is spacecraft bourne the launch restrictions limit the power to 10 Watts.

> Gary asked previously if 4x the power would send the signal 2x the
> distance. In general, the answer is yes when all else is equal. Every
> time the distance from a signal source out there in space doubles its
> level drops by 6 db. If space loss is 183 db at 10,000 miles, at 20,000
> miles the loss is 189 db.

OK at 10,000 miles the signal is

+40 dBm + 60 dB + 30 dB -183 dB = -53 dBm

> The gain of a dish is proportional to its diameter in wavelengths
> squared. How about a larger dish?

If you have 20 Million Dollars to splash around then you can have a slightly bigger dish, or you can hire Joderel Bank. Of course you will need more than the 20 Million cos once you've increased the Range by a number of dB you'll

have to pay the staff and the running costs of the station for the additional time. Remember that if it has already taken 50 years to get out to where you are and the Spacecraft vector velocity away from Earth has remained constant at 13,000 m/s to double the distance is going to take another 50 years. also the signal rate of decrease is falling off daily. by the time that you get out to this distance the signal is falling off at something less than 0.00001 dB per day (I might not have enough naughts in that, I just guessed the number, but as an exercise you can calculate the rate of signal decay with mission elapsed time.)
So be prepared for a big bill.

OK when you find the extreme range calculate the RTLT (Round Trip Light Time), you can use 3 x 10^8 m/s as the velocity of propogation.
When you derive this number you like me will be amused when you next see Captain Pickard phoning home for advice.
Imagine that you are on the Space ship and your means of communication is exactly the same as posting to this news group. Think how long it takes to get a reply to your posting and multiply the delay by a good bit, (if you know the RTLT you'll know how long a message will take) the 3 second delay between here and the Moon made life difficult, imagine how much more difficult would be the delay to Mars at its closest approach to Earth, Robot Wars control is nothing compared to that problem. Think how you might overcome the space delay for an unmanned mission to a planet.

> A highly directional antenna needs to be located so it isn`t aimed at a
> big noise source.

Assume that the whole aperature is illuminated by the 4°K background noise of the universe and is included within the 12°K Ts

>Point it at the sun`s 6000 degrees K surface and
> receive 8.28x10 to the minus 14th watts or -101 dBm.

The background noise of the Moon at 150°K , the moon subtends an angle 0.5 degrees at the Earth sufficient to completly fill the 0.3° or 0.1° beam width of the Earth antenna was sufficient to degrade the expected signal to noise of Surveyor by 10 log (150/40) = 5.7 dB, Real time TV from Apollo was nearly not a goer until the knitted gold wire parabolic dish was made to increase the ERP of the Apollo signal to be within the 30 dB communications margin.

>This happens to
> satellite earth stations in the spring and fall for a short time each

What is the duration of this seasonal effect?

> The greater the distance between transmitter and receiver, the greater
> doubling the distance increments the distance. What`s the limit? Is
> there any limit?

I am asking the limit of range for a 10 Watt unmodulated carrier and a 12°K Ts.

assume a practical dish on the space craft gain 30 dB.
Dish gain for receiver 60 dB.
The limit is set by the noise threshold of the Receiver and the launch
constraints upon the Spacecraft transmitter being of the order 10 Watts.
More power bigger power supply, (for this mission only and onboard nuclear
generator will fit the bill cos the Sun is gonna get so far away that Solar
cells will not provide any power at all.)

Get a much bigger Rocket and you can carry a bigger spacecraft and may be a more powerful transmitter. Of course improvements in Transmitter efficiency will have the same effect as a bigger Rocket, but at a fraction of the cost. The same is true of Ham communications, a little money spent on a good Receiveing antenna and a good Noise Figure receiver (reasonably cheap these days) is worth a lot of money spent on Linear amplifiers. Of course at low HF the limiting factor is Sky |Noise and for a given path in order to improve the communications Signal to Noise ratio Only more transmitter power and a better transmitting AE will acheive the desired improvement in a given communications mode. Change the mode of communication to say PSK31 and the same old transmitter will have to have its power wound down to pack in the numbers of transmitters that can now occupy the old bit of spectrum and still have excellent communication margins.

But to really get a feel for flying a Deep Space spacecraft do the sums
yourself and feel the vastness of space.

Hi Gary,

No resistance? That begs the question: why do you expect it for this scenario (this is the danger of switching the focus and maintaining the same argument)?

When an electron encounters the phosphor, it reacts at the atomic scale (as so it does with the tube's plate) where the energy is converted into a photon. Given that the plate of a triode does not exhibit phosphorescence (normally), there is no option to total conversion of the Beam's inertia into heat (the plate dissipation factor). The resistance in the phosphor is found in the efficiency of its conversion of an electron to a photon, but now we introduce yet more parameters where the simple Triode sufficed. If the new scenario presents a completely efficient conversion (unlikely) there is no heat shed.

This is simply another Q issue. However it is the Q of an atomic resonance related to the De Broglie Wave.

As I reach up and touch the screen of my monitor, I note that the temperature is in excess of ambient. This heat is not coming from the filament, but there is admittedly a component of it due to the electronics within the enclosure. Perhaps you should re-consider the issue of this being "un-noticed." Then again, perhaps not. You certainly have the background to perform a caloric measurement, but this tangent is off-scale.

Up to about 1-10 GHz in ordinary coaxial cables (ones using decent insulation like PE or PTFE), the loss is almost entirely series, due to conductor resistance. Above this, dielectric loss becomes dominant. (The dielectric loss increases about linearly with frequency, while the resistive loss increases as the square root of frequency. At low frequency, the resistive loss is much greater, but because of the different slopes, dielectric loss eventually catches up.) But you'll see the rising TDR response also on things like PC board traces. It really complicates the job of determining a line's characteristic impedance with a TDR, which is something modern PC board manufacturers are increasingly being asked to do.

It's a good assumption that the cable is a linear device, so the final resistance measured by any means should be the same. However, I'm not really interested in haggling over what kind of instrument you'd use to make an impossible theoretical measurement.

I don't know how to sort all resistances into dissipative and
dissipationless, but I would like to see someone who does
substitute one of his "dissipationless" resistors for the source
resistance in a voltage divider and use it to prove the complex
conjugate theorem analytically. It seems that some of us believe
that because the maximum power theorem is proven for ordinary
dissipative resistors that that automatically proves it for everything
else that has units in ohms.

I don't think the problem of misapplication of the maximum power transfer principle is so much one of dissipative and non-dissipative resistors as it is using the wrong model. The principle is easily shown only for a Thevenin or Norton source model. But these are certainly not adequate models for a transistor or vacuum tube output. Special care has to be used when attempting to use linear models for nonlinear circuits. Linear models can often be useful, but you always have to keep in mind that they really don't represent the real circuit and are at best an approximation and then only under some set of very limited conditions.

Hi Roy,

Yes, you are right. I have used dynamic resistance as a filter
element in the RC decoupling of power supply and active device (the
voltage rail to an OpAmp). It works wonderfully in passing enough DC
current while inhibiting high frequency spurs. That is, I typically
use a diode in series from the power supply feeding a cap that in turn
is the voltage rail source (the typical device decoupling). The diode
presents a high Z to RF and a low R to DC (acts like inductive
reactance, but without the storage). If I recall correctly, even the
roll-off is not the classic 6 dB/Octave (but rather much better if
memory serves).

I would have to say that if it exhibits a quasi reactance and no
storage, there must be heat involved. I have likened it to an
inductor, but the mechanics of the depletion zone would suggest in the

high RF I had two capacitors in series and the diode having a smaller capacitance naturally exhibits the greater drop to spurs. If this is the correct operational criteria, then there would be no issue of heat.

So, there is a quasi inductor or a real capacitor that might be argued. Neither is wholly supportable - leave it to non-linear devices to throw a sabot into the gears.

I could be wrong but I think you might be comparing apples and oranges.
BNC and SMA should be connectors that connect to a transceiver. The NMO
mount should be used to mount an antenna. Again, this is to my
knowledge.

I 3 NMO mount antennas for my truck and car. I started out using the
mag mount much like you. I found that I like the NMO mount very well.
I now have two permanent mounts on both vehicles.

[SNIP]

Fugetaboutid! What kind of "cop out" is that?

Reg, you can't get off so easy, and neither can Tom. Come back here and fight it out!

Theory versus Practice, Mathematics versus Laboratory, Software versus Hardware, Aristotle versus Plato, Ali versus Liston...

We want it now!

Reg what is the mathematical model that you are using for Q, and Tom what is the manufacturer, model number, serial number and last calibration date of your Q-Meter?

Best,

-Peter K1PO

>> 1. Does SWR even matter for reception?

>SWR does matter for reception.

Maybe, but on HF, probably not. On HF, with any kind of a reasonable antenna and feed line, the system sensitivity is not determined by receiver noise, but by external noise (atmospheric, local noise, etc). SWR on the feed line will result in attenuation of the signal you are trying to receive, but it will reduce the signal and external noise by the same amount. As long as the resultant signal and external noise is much greater than the receiver noise, the S/N output of the receiver remains essentially unchanged with such external "attenuation" applied. The change in overall S/N is usually fractional dB on HF.

In fact, adding attenuation in front of an HF receiver can actually help improve reception, not by changing S/N, but by reducing the level of strong signals outside the receiver passband below the receiver's non-linear range. If you have a good antenna system and operate in major contests, you may want to add attenuation to your receiver. It matters little whether the attenuation is in the form of an attenuator or in the form of SWR on your feed line.

>Your mag mount may not be directly connected to the car body, but the
>negative power lead to the battery is, in turn the shield of the coax is,
>and there is the capacitive coupling through the mag mount to the body.

On VHF, the capacitive coupling of the mag mount will predominate. Even on HF, it is the primary coupling mechanism most of the time. I have a 4-magnet mag mount for my HF mobile whip and it operates just fine on 20 meters and up, but on 40 meters, I get a lot of "RF in the shack" problems. On that band and lower, the series capacitor in the capacitive coupling of the mount to the vehicle body is too small. I use a combination of a ferrite common-mode choke on the feed line, right at the antenna, and a short jumper from the mount "ground" to the vehicle chassis.

Now, with my "Deathmobile," I wonder if the rust is adding any non-linear factors. :-)

What's wrong with "radiation resistance", what's wrong with "surge resistance", what's wrong with... ?

None of those descriptive terms dare to juxtapose the lack of dissipation with dissipation.

Get with it... "dissipationless resistance" is an abomination and should not be allowed.

Some amateur hack article writer hired by a sloppy IEEE editor came up with that "crap" it was not critiqued by anyone who understood Electrical Engineering and the English language, and you help to perpetuate it. What?

I think you mean a SO-239 (259?) connector. Same thats used on some CB
Antennas and some Amateur anttennas. I use NMO haven't had any probs.
Check out Comet's website and you see the antennas that have both mounts.

Roy, W7EL wrote:
"Is transresistance (amplifier output voltage divided by input current) dissipationless?"

Just as transconductance depends on vacuum tube amplification factor, transresistance depends depends on gain. More change in output voltage will happen with the same change in input current if only we have more gain.

Transresistance does not quantify an amount of heat produced by an output voltage, nor does it represent a load value that does not directly produce heat. Transresistance is a type of "ringer"

Roy also questioned the series resistive part of Zo. Like the conductive and other shunt dielectric losses, the series resistance of the transmission line is dissipative.

3685. Internal Ant. Tuner with External SWR Meter???

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-23 04:15:46 UTC
From: Salesman <Salesman@Store.com>
Message-ID: <38785C11B9EB5DCF.5CA2D31E5FB0652D.63A03E2CD421D450@lp.airnews.net>
Source record: 169758

I have a Yaesu FT-990 which has an internal antenna tuner which I believe will help minimize the SWR if it is below about 3:1. I use a Gap vertical antenna which matches by itself pretty well on most of the bands. I also happen to have an MFJ Versa-tuner in-line with the antenna which I run in by-pass mode just to monitor the SWR.

I notice that If I kick in the internal tuner in the radio it will usually bring the match to a flat 1:1 on the SWR meter on the radio but the SWR meter on the Versa-tuner may still read 1.5 or 2.0 to 1.

The SWR differential seems to be higher on the high bands such as 10 meters whereas down on 80 meters the 2 readings tend to be much closer.

I guess my question is: Should I have the Versa-Tuner in line (even on by-pass) and if so, which SWR reading should I believe?

Any insight would be appreciated.

Peter, K1PO wrote:
"None of these descriptive terms (radiation resistance, surge resistance, average resistance value resulting from part-time conduction) dare to juxtapose the lack of dissipation with dissipation."

Peter raises a good point. There is widespread supposition that resistance is identical to a resistor and a resistor is a heat producer. This is wrong. A resistor does produce resistance (voltage to current ratio) and it does produce heat, but a resistor is a special case. A resistor immediately converts all the electrical energy it accepts into heat. Other types of resistance are in-phase voltage to current ratios which don`t immediately convert electricity into heat.

I`ve been surprised that some serious authors have declared that resistance is the ratio of voltage to current at which the conversion of electricity to heat takes place. They are wrong because they don`t point out that resistances exist that do not produce instant heat. Many accept and repeat this wrong information.

IEEE just tried to bring order from chaos.

It does not hurt to have the SWR meter in line. In fact, both readings are probably correct. The internal SWR meter is giving you the SWR that the radio sees, looking into the internal antenna tuner. If this is all working correctly the SWR you read here will be very close to 1:1. The external SWR meter is reading the actual SWR of the line and antenna, which reflects the "real" SWR.

Source record: 169762

Thanks Bob, What you said is kind of what I suspected.

But what does it mean if I remove the external meter and the internal meter on the radio still reads 1:1? Is the internal tuner just trying to match the short distance between the external meter and the radio and not affecting the system past the external meter? If the external meter is not there, am I matching to the entire antenna system? Is this then the "real" SWR?

The dynamics here are kind of confusing to me. It seems that he external meter (Versa-Tuner on by-pass) should have some effect on how the radio's antenna tuner views the antenna system.

Point is in an infinite lossless line the wavefront moves ever forward generating opposition in the same way and amplitude.

Reg will need to refresh the battery in his ohmmeter from time to time to keep up the energy supply to the ever hungry transmission line.

Your Versa-Tuner is showing you what the antenna looks like. The 1:1 SWR your Yeasu FT-990 is showing is what the transmitter thinks the antenna looks like. I would remove the Versa-Tuner and use a dedicated two needle SWR meter is you feel that you need to. Otherwise don't worry about the post Yeasu antenna tuner readings. The built in AT is doing it's job and all else is unnecessary.

The antenna tuner does not change the SWR between the antenna tuner
and the antenna. It only changes the 'SWR' between the tuner and
the transmitter. The external meter (in bypass mode) is reading the
SWR between the tuner and the antenna which cannot be changed at
the tuner end. For any given frequency, the SWR between the antenna
tuner and the antenna can only be changed by doing something at
the antenna (assuming an unbroken run of transmission line).

> well will that work as a ground???

Michael,
Let me ask you this, is the fence connected to your neighbor's
fence? If so, it's a bad idea to use it as a ground. Since the
ground is part of your antenna system, your running your antenna
around your neighbor's house...not good. The fence really doesn't
ast as a very good ground anyway, depending on how you make a
connection to it. If you don't bond all the top rails to the posts,
and posts to the 'links', you have a variable ground system... that's
not good either. It's a tempting idea, but...

The ATAS-100 antenna MUST be well grounded or the internal circuitry will fry. I found this out the hard way. The symptom is usually that the antenna will extend fully, and then stay there refusing to retract. If still under warrenty, Yaesu will fix it.

But,

Is transresistance dissipationless? Or do we now have three kinds of resistance, "dissipative", "dissipationless", and "ringer"?

I disagree that the series resistive part of the Z0 of all transmission lines is dissipative. A lossless line has a purely real Z0. How can a lossless line contain a dissipative resistance?

both

PI is 2 m location given as Barkway. I remember something hanging onto our
tower when I was with PYE. Lightening struck our waveguide at that site and
took the circuit breaker right off the wall and left a hole about 4 foot
square.
PY is 70 cm and location is given as Cambridge, I have no idea if it is at
the same site as the 2m repeater. Probaly up on the Gogs. :-)

> with just a few watts and on rx they're fully quieting with a good strong

Source record: 169674

The value of Q, whatever it might be, is not of any direct practical use. It is just a ratio. It may be used to calculate or estimate some other circuit parameter. In the case of quartz crystals the other circuit parameter is usually the series loss resistance which, in any case, can be more easily measured directly.

An accurate way of determining coil Q, if anyone should insist on knowing the value of Q, is to measure the coil's loss resistance at resonance using an impedance bridge - then CALCULATE it !

Why am I reminded of the method of determining ground conductivity by setting up a high power radio transmitter and measuring ground-wave field strength at various distances up to several hundred miles ? Having tediously determined ground conductivity it is then possible to predict field strength at various distances from a transmitter of known power output.

But it does keep the philosophical conversation going ;o)

Pete, there is no controversy. Please desist from stirring it up.
Joke, joke.

I do not have a Q-meter. Like SWR and S-meters I don't trust them.
I have my own, more reliable methods of determining Q.

But in any case I (and very few others) seldom need to know the
value of Q. It's not a particularly useful quantity. As I have said
elsewhere, Q is just a ratio, an intermediate value in the
calculation of some other parameter of more practical interest. It
also provides a topic of conversation.

My relatively recent interest in Q arose only because I wanted to
check the accuracy of some software. Before throwing my SOLNOID2
program to the wolves I wound 20 or 30 coils of various dimensions
to check what you would refer to as 'algorithms'. The algorithms
were developed from basic engineering and mathematical
rinciples - the tools of any electrical/mechanical engineer worthy
of the name. On these coils, 1 inch to 5 feet long, 1 inch to 6
feet diameter, I determined, where feasible, inductance,
self-resonant frequency and that nuisance parameter Q. Having
served their purpose I tossed the scribbled measurement results
into the garbage bin.

So I do not have a calibration certificate for a non-existent Q
meter. But having during my career set up from an empty floor an
electricaI standards and calibration laboratory on an echelon
imediately beneath the British National Physical Laboratory
(equivalent to NBS), I am familiar with assessment of statistical
measurements uncertainties and the need for traceabilty to national
and international standards.

3705. Advice on grounding for end-fed ant?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-23 15:10:53 UTC
From: jwg6@cornell.edu
Message-ID: <975uht$383$1@news01.cit.cornell.edu>
Source record: 169679

Scenario: Putting up end fed Zepp; station is located in 40-ft trailer (mobile home); one end of the 130' wire will be supported at the edge of the bldg. Feeder will be 450-ohm ladder line, going to balanced coupler. Either that, or a single wire feeder to a matching network.

Problem is, how to provide a proper gnd for the coupler. I don't think the water line coming into the home is accessible. The plumbing is plastic, for the most part. My options for grounding might be:

-use the aluminum siding (but the panels are probably not electrically continuous across the bldg.

-use the electrical service ground

-use a counterpoise(?)

An 8' ground rod is probably out of the question, at least at this time of year. The place is a rental, so the installation should be as discreet as possible. The ant. itself will be thin, like #26 and so not very visible. I intend to use it mainly on 75 and 40m.

Not sure how to proceed, and looking for any suggestions...

>Could someone tell me what the coax running from the
>> antenna to the radio is? (RG-58)?

It's been a few years since I did car radio repair, but back then the coax was definitely NOT RG-58 or anything similar. They use a hair-fine center conductor to reduce capacitance per foot. Using "ordinary" coax will upset the input tuning especially on AM.

A friend has a GAP and he does not like it. Kind of flimsy. Does not perform well in his installation. I have a Hustler 5BTV (80/40/20/15/10) that has served well for over 15 years. It needs a good counterpoise or several ground radials, although it will work on just a pipe and ground rod, elevated with radials cut for lowest band work well. Good lower angle for dx. I have Cushcraft R7 that has its own 7 radial counterpoise and covers all bands 40 to 10 meters. It works well and should be elevated--higher is better--but you can make contacts with it about 8 feet or so off the ground. Good low angle for DX. Both 5BTV and R7 have good band width without tuner (not recommended) but gets narrower the lower in freq you go. Of the 3 antennas you mention, the Hustler is by far the most rugged and easiest to install if you have space for radials. The Cushcraft would be next, and may perform a bit better--but not sure about the new ones. You can find good used R7's for about $100.00 The Hustler 6BTV covers 30 meters as well and elimiates some capacitance hats for a more streamlined look.

Source record: 169684

A few weeks ago, while taking a short "reading break" from a DX pileup, I was flipping through one of the electronics trade magazines and browsed an article.

The premise, if I remember correctly was that turn-to-turn capacitance in an inductor was more-or-less a myth because, and this is fuzzy, there wasn't a significant difference in signal phase and amplitude between adjacent turns and self capacitance was really just capacitance between the inductor and the measuring instrument.

I said to myself, "Self, that is interesting you should study this more later." Unfortunately, the library was rearranged before I remembered to look this up and now I can't remember where I saw it.

Any comments?

I've read catalogs and handbooks until I've completely confused myself, so it's time to seek the opinions of others wiser than I...

I have a 19' fiberglass boat. I'd like to put my 2M multimode onboard so that I can fish, boat and play radio at the same time. I'm leaning towards stacked HoLoops from M2 for SSB, but I'd like a simple vertical for working FM. The problem is obvious: very little ground plane.

I'd really appreciate your recommendations! Thanks!

I think know what you mean: antenna is female and threads onto a
stud about 1/4 inch in diameter and 1/2 long ???. I have two of
them hanging in the garage which I use with 2 meter quarter-wave
antennae on my motorcycles but can't recall who made them. I got
them from HRO about 10 years ago. I think their small "L"
brackets were meant to mount to the lip of a car trunk with
sheet metal screws. <http://www.hamradio.com/> Good hunting.

Arrow antennas makes a very nice dual band j-pole that would fill the bill nicely.

URL:

http://hometown.aol.com/Arrow146

We have several up in this area and they work rather nicely. Built like a tank, but light weight. Being a true half wave antenna, you don't have to worrry about ground...can be mounted on either a metal or insulating mast and you get two bands for the price of one. Price is in the high thirties.

I may sound a little too angry, the thing is, I want my 18 dB .
Made a 29 turn antenna and it's performance is bad.
Structure is made of PVC, which should be ok,
according to the microwave oven tests.
Suspect the matching.

http://www.tuc.nrao.edu/~demerson/helixgain/helix.htm

They simulated 10 000 helixes and their data show,
that 18 dB is realistic.

Look at the data which show gain versus length
and gain versus diameter.
Very interesting, and we can see that mechanical
tolerances are to be kept low.

Am working on that, will buy Kraus' book.
This is a *must* anyway, has to be in every antenna book collection
:-)

thanks,
w.

That's an interesting thought. But extending the argument, it appears
that inductors couldn't be self resonant. But they are.

The most easy to manufacture match,
uses the triangular microwave transformer strip
which I mentioned as 4.) in the first posting.
Look, how carefully Jhecker hides the details <grin>
Strip is 73 or 71 mm long, why?
How do I calculate the strip for a DIFFERENT FREQUENCY?
look at the photo, where it is half-covered.
How did jhecker calculate the 71 millimeters?
This is more than a quarter turn but less than a half turn.

Cannot copy.

Hi Ed,

Imagine his surprise if it worked better using the usual radials.

The problem with chain link is that the wire mesh is not necessarily
conductive at the intersections of the chain links. In fact, there is
every opportunity of generating spurs and encountering problems due to
the variable nature of conductivity (and issues of corrosion at these
cross points introducing intermod). However, having said that, I did
observe one fellow at field day had considerable success using a ball
field backstop as his ground connection to a balloon launched vertical
for 160M. He surprised other 160M users with his big signal (they,
unfortunately used the usual radials).

Go figure. ;->

Hi Wes,

Comments follow.

Strange observation indeed, and probably argued from a perspective
where this issue is marginal at best (in other words they don't worry
about it because it isn't a problem at their scale of operation). I
say this because of their provisos offered insofar as signal phase and
such (rather an exotic consideration that does not exist at all
scales).

There are clear and simple solutions working in a billion dollars
worth of gear. In my own 6M rig (a Motorola mobile converted from
public service) are a string of at least 6 shielded inductors that
each show considerably more Q than if they were simply sitting on an
open PC board (or in free space for that matter). There is a better,
technical name for them, but I am not close to my resource to
resurrect that term right now. The point of the matter is that all
capacitance is overwhelmed by the surrounding shield, but that shield
is made part of the resonant circuit and would certainly swamp the
inter-turn capacitance.

In the Nav, I taught a course on what was then called the TED and the
RED (UHF transmitter and Receiver). One of the amusing tuned circuits

was a simple metal post in the middle of a cavity (no, the cavity was not resonant in the conventional expectation of modes excited by the physical dimensions - more probably another example of my 6M rig's design). No turns at all, nor any capacitors. Knowing the specs demanded by the Nav, I would say that the Q was very good.

get a marine band VHF antenna that has a plain steel whip about 36 inches long. (Some have much shorter whips and some are enclosed in Fiber-glass - ignore those) . Extend the top of the whip with about 4" of stiff wire. Set it all up with SWR meter in line. Use lowest power setting. Using 146.1 Mhz . Snip bits off the wire extension until you get lowest SWR. [probably end up with around 3 inches but easier to start long and snip than start short and try to add)
Bingo..you're in business.

Hello All,

I have two Cobra PR1000 2-way portables that I want to use in vehicles. I'm looking for a magnetic mount antenna for a channel in the 462Mhz range. Know where I can get one? The radio has SMA female connector on radio. Or do I have to make it? Should I just buy the $25 special at Radio Shack and then try to cut (tune) it myself? And find a BNC to SMA female adapter? What should the length be?

The Cobra literature mentions being able to attach a mobile antenna for use in a car but, so far I can't find anything on finding one.

Jeff

As I remember, it's a 93 ohm cable designed to have a very low capacitance.
And Bill is right if you use anything else the performance of the radio will
be hurt. The reason is that a car antenna is more like a capacitance probe
or an active antenna than anything else.

Get under the trailer and find the steel I beam frames. There should be at least 2 of them, 4 if you have a "double-wide." Make sure these are bonded together with copper braid or strap. Grind off outer paint down to bare metal and use star washers to get a bite. Hook up a ground rod at each end of trailer and tie into beams. Pull back carpet and make a hole in the floor near base board and run you ground braid up though the hole to your tuner and other equipment. Hopefully your radio set up is near the service panels and service ground--tie all that together to fram as well. The bigger metal foot print you can make the better your signal will be. Don't let the "hot" wire touch any thing metal and use stand off insulators if necessary. What you are basically doing is making a "big mobile" installation--so picture a big car with a big (130 foot) whip on it!

Roy, W7EL wrote:
"I disagree that the series resistive part of Zo of all transmission lines is doissipative. A lossless line has a purely real Zo. How can a lossless line contain a dissipative resistance?"

I wrote: "the series resistance of the transmission line is dissipative."

Roy is right. I used the generic word (resistance). I should have used the more specific word (resistor). Then: the series resistor part of the resistance of a transmission line is dissipative. Isn`t there a redundancy there? Or: the copper loss in a transmission line is dissipative,

Point is, a transmission line`s distributed inductance and capacitance don`t cause loss, but they do cause a characteristic resistance which is lossless. Characteristic resistance is built of distributed inductance and capacitance, both of which are lossless in their pure forms.

Real conductors in transmission lines have loss but it can be so low as to be disregarded in many practical situations.

I know which resistance I mean by the context I write it in. Why doesn`t everyone else?

Best regards, Richard Harrison, KB5WZI

Hi Zoran,

That big truncated cone of mesh wire behind the umpire, behind the catcher, behind home plate, in front of the pitcher, in front of second base, in front of center field, in one corner of the base ball stadium (or a school ground play field).

It is so called because it is at the back of play and stops the ball if the pitch is wild and is missed by the catcher (and does not strike either the batter, the catcher, or the umpire). It also stops tip fouls and pop ups on occasions.

In school grounds it is often extended out along both base lines to each team's "dug out." This was just such the case for the results reported above.

Hi Richard,

I will weigh in (again) to this "dissipationless" term without merit.

To answer your last question first, context is unnecessary if you simply state that the resistance is reactance instead (which no one would argue with the unit being Ohms).

This absurd differentiation with "resistance" ignores the established dissipationless aspect already part and parcel to reactance.

When Thevenin is confused by users with requiring an R to work, it is pointed out that the correct definition is Z. If a Thevenin source does not apply all available power, that power which is withheld is done with reactance - who needs to create a special artifice of dissipationless resistance when reactance already covers that, is part

of Z, is measured in Ohms, and is already understood to be non-dissipative! This absurd distinction of a separate meaning for "resistance" is simply gutting the Lily and pandering the Rose. Consider, as Roy suggests elsewhere, we have resistance, reactance, and non-dissipative resistance? How does one distinguish between reactance and this non-dissipative resistance? As much as they are similar, I have not observed any mention of how they are different. If they are not different, then one term is unnecessary. I vote "dissipationless resistance" off the Island.

Now to weight into the transmission line Z, which is described as being 50 Ohms (or choose your own). The 50 Ohms comes from where? I think I saw Gary quote the standard sqrt of L/C. Do these separate reactances for each (L and C) not exist? Of course they do, and they are equal and opposite. Can we imagine that they may each be 50 Ohms? Even with Tanks, there is a Z that is exhibited that is unrelated to the loss presented by any R present (well maybe not entirely unrelated if you choose a poor Tank design). A Tank circuit for a Triode is not the best design solution for a Tetrode and the difference is in the Z of both the Tube and the Tank.

OK, back to the line. At 50 Ohms, and without the annoying R, there is no conversion to heat (BFD!) and yet to satisfy the 50 Ohm spec the line must be infinite, or terminated in a carbon resistor of... 50 Ohms! Either way, the signal is not recoverable and completely lost - or in the words of the english speaking world: dissipated. There is only one exception: where the carbon resistor is replaced with an active device that in turn dissipates (turns to heat for engineers who cannot cope with english and need remedial aids to communicate) that applied power for the purpose of detection and amplification. In nearly every instance, that active device sees a 50 Ohm carbon resistor terminating the line anyway! (Are receivers heat amplifiers? I will bet some, on a summers day in a small airless shack, may think their linear is.)

And to turn the thread back to the topic, Walter and the Triode, as I have already posted elsewhere, the Plate is a perfect example of a nearly 0 Ohm structure that turns current into heat. Some in this group refuse to acknowledge this fact because it would dash their logic of a source not containing a dissipative (their words) resistance. And yet such physics is classic and satisfies every known definition offered by every correspondent to this topic. For these individuals, I must suspect that there is a yet undisclosed third meaning for "dissipative" for which the Plate Dissipation Factor is not related (yeah - sure).

One of our references, Terman, uses the term "Real" resistance when he describes the Z of a line. Note he did not use "dissipationless" except as an adjunct to explain that the power loss was not to heat. And just what distinction does Heat have in this, or any other regard? Terman merely comments on this as a distinction to be noted but not

taken as a religious expression. What does he mean by "Real?" In just the way we would interpret it: not reactive (and he specifically says so). Geez - that's too simple! Converted to heat or lost to outer space is indistinguishable to the transmitter or the receiver (which by definition can't observe the signal anyway and we must insert an artificial observer with a thermometer to confirm - what happened to Occam's razor fellows?).

And one last tag. If EVERY living person on this planet (and a few of the dead ones) had an antenna and a radio and was listening to you without any problem of propagation (yeah impossible - I said "if"). And you were transmitting 100W and each and every receiver indicated 10dB over S9 (yeah impossible - I said "if"). Then, something like 90% of the power transmitted would be lost to dissipation (and no one could argue if it were spent in heat or simply trapped in a bus queue). The difference here is that the english speaking world would understand exactly what dissipation meant, and the religious sycophants would be running the length and breadth of the terrain with thermometers to proclaim a distinction without merit. In the process of their proselytizing, they would dissipate not only the heat of their frustration, but also dissipate their credibility.

I think that you brought up the kinetic energy of an electron ploughing into the anode of a vacuum tube and releasing its energy in the form of heat. I was attempting to give an example that might be more familiar to the younger contributers of this group. Many still have cathode ray monitors and most will have seen a TV set with a CRT. Here is a prime example of an electron accelerated to with several kilovolts and then brought to a sudden stop in a coating of material that has the property of liberating light when excess energy is applied.

I believe that the purveyors of the term "dissipationless resistance"
use it to describe a quantity for which the voltage and current are in
phase -- as opposed to a reactance in which they're in quadrature. That
is, as I understand it, "disspationless resistance" is purely real in a
mathematical sense rather than purely imaginary like reactance.

Anyone have any experience with the Transco antenna switches--the style that has N fittings and use a stepping switch mechanism to index to each port (normally made with 2 to 6 ports). I picked up a few on eBay and I am thinking of using them on the top of the tower to select various VHF/UHF antennas down to one good hardline going to the shack..

How reliable are these units, are they suited for long-term exposure to elements (temperature, I will mount it in an aluminum box)? I am looking for something that approaches military quality and needs zero maintenance. Appreciate any advice.

Reactance responds with current which eiher leads or lags the voltage across it by 90 degrees.

Resistance responds with a current in-phase with the voltage across it regardless of whether the resistance immediately converts the electricity to heat or does not.

Hi Roy,

You are going way out on a limb to suppose what someone else "might"
be thinking. But it serves.

The Real resistance that Terman speaks of characterizing the Z of a
transmission line is neither reactive nor does it decelerate charge
(how could it? this imaginative line is loss less and infinite). As
such I and E are always in phase (which is a derivative principle, not
a first principle of dissipation).

But when we examine the source for dissipative loss, and find it (real
heat, first principle of dissipation), we are presented an argument
that devolves to the logic above and appeals to an artifice creating a
reality. To see the conjectures that the R in a source Z measured by

Walter, in a transmitter, is actually evidence of dissipationless resistance is a logical perversion.

This, of course, is my not so mumbled opinion.

73's
Richard Clark, KB7QHC

p.s. you may note a change in my ISP.
@Home is a blast (as long as my neighbors don't catch on I suppose). My mumbling now comes at you at 1.67 MBaud (but the typing doesn't seem to be any quicker).
A middlin' state of the art 866 MHz Pentium 500 MB RAM system with a cable modem on the open highway can support full screen video on demand and still leave more than 50% of the CPU horsepower available for other work.
Now when I say video on demand I mean I can watch the classic B&W comedies of 50's TV and Hollywood Films with about the quality of a VHS tape in its 6 hour format seen the tenth time. A shameless plug:
http://www.liketelevsion.com
is a source of a jillion shows and films in full length.... I should burn out soon.
and to cap it off, it costs no more than the old way. Less in fact.

3744. question on theory

Newsgroup: rec.radio.amateur.antenna

From: ogardner@uiuc.edu
Message-ID: <cKHl6.4909$dL4.61849@vixen.cso.uiuc.edu>
Source record: 169717

An earlier article describing a new feed system for a W8JK antenna (by Zimmermanin QST Jun 99...with a dimension correction in July 99) prompted me to press his idea further. He moved the feed points away from center to get a higher resistive feed point. He chose 25 ohms which he converted to 100 ohms via an electrical quarter-wave section of 50 ohms. (i.e 25 is to 50, as 50 is to 100). He then paralled the two similar configurations to get the 50 ohm feed point, apparently unbalanced to accommodate the 50
ohm feed-coax.
I saw later reference by him, where he suggested a W8JK wire antenna where he moved the feed points out to the 100 ohm resisive points (16.5% of the way from the ends), both on the same direction from center, and fed them with 100 ohm balanced transmission line (hard to find?), with one of them transposed, of course to get the two W8JK half-waves out of phase. These were joined somewhere to provide 50 ohms balanced (two 100's in parallel), but then I suppose a choke-balun would be in order.
He aroused my curiosity, and I wondered how far this scheme could be pushed.
On EZNEC, I found the positions for 450 ohm feed points (W8JK-type), which occured at 6% of the way in from the ends. (458 -j15) for a SWR of 1.03 referred to
450 ohm balanced line. These are paralled at some point (one transposed) to offer 225 ohms, which is suitable for a 1:4 unbalanced-to- balanced ferrite balun.
I was thinking of the old days when many hams used "end-fed ZEPPS" and was always wondering what the theory was.
On this 450 ohm version, one would like to think that feeding this "450 ohm resistive" load shown by EZNEC would mean equal currents in the 450 ohm feed lines.....and that they are not radiating. BUT MY INTUITION tells me that it is unlikely this can be true, when 6% of the half-wave attaches to one side, and 94% attaches to the other.
Things really get temperamental in EZNEC when you try to find higher resistive values even closer to the end.
SO WHAT'S WRONG WITH THIS PICTURE ??

Hi Richard,

So, I will agree there is a discriminating factor of phase that has no impact whatsoever on the issue of dissipation (except for boundry conditions). Which is to say that an X satisfies as easily as an R for a Thevenin Source Z (or an admixture of those three) and that R is clearly distinguishable, and unambiguous by clearly revealing itself in heat which in turn is evidence of dissipation. Further, that there is the speculation of a "dissipationless" resistance as a physical reality, and it somehow answers to the name R in this Z - THAT has not been demonstrated.

Your mileage may vary. ;-)

But why would a cop car need an Inmarsat terminal?

There are also GPS antennas that look quite similar, which makes much more sense since automatic vehicle location systems are commonly included in cop cars.

Ahhh, please excuse my ignorance when it comes to our national pastime. It's the euro-trash in me: the only sport I follow is basketball. Now, if you had said that his radials were "in the paint" or that his signal was like an "alley-oop after a three second violation", that would have been a different story.

Thanks and 73 .... Zoran WA7AA

How do you expect to get such attenuations when cable leakage is much
more than that above audio frequencies.

Reg:

As you know, I heartily agree with your comments/sentiments below on SWR and SWR meters. Seldom are they used properly, and seldom do they indicate anything about the "reality" of the wave conditions of antennas and lines.

What is more, besides giving indications which are irrelevant and almost meaningless, they also have a great potential for causing ElectroMagnetic Compatibility (EMC) or ElectroMagnetic Interference (EMI) when left "in line" because the "diodes" used in the devices create a whole spectrum of harmonics when they rectify the residual RF that they use to operate the SWR circuitry.

But... on the other hand don't you agree that leaving an SWR meter "in line" is somewhat "comforting"? They do have a certain appeal to those who need "indications" that things are happening. Something like the "ignition" light on the dasboard of your automobile, completely irrelevant for most purposes... but comforting.

Having those needles on the SWR meters bounce up and down across the scales of the meter faces while you are talking or keying the rig, gives a visual indication that "something" is happening. It lets the operator know that RF is flowing somewhere. I believe that is the "appeal" of so-called SWR meters.

Sort of like having one of those old fashioned "On The Air" signs that illuminate whenever the transmitter is keyed. Heh, heh.

Of course an "On The Air" meter actuated by the PTT switch or CW Key would have a lot less potential for causing interference.

An operator friend of mine was having problems interfering with the family TV reception whenever he operated his ham radio. He always ran with an "in line" SWR meter. I advised him to take the "in line" SWR meter out, and presto the interference dissapeared!

The readings on the SWR meter were irrelevant to his situation anyway, he just liked to see the "indication" of power output. A small pilot light bulb tapped across the antenna feeders would do as well with a lot less interference.

I say, get rid of those "in line" SWR meters...

I've Used both the MFJ , and home brew small transmitting loops several
times. They work supriningly well for their size, but are still down from
most dipole installations.. if you can get a dipole up say at least a
quarter wave it will do better. but if you cant the the small loop will
give plenty of
contacts.

Your intuition is correct. The more unbalanced the dimensions of the 1/2WL dipole are, the more unbalanced the ladder-line currents will be, and the more the feedline will radiate. The radiation pattern will also be affected.

Wouldn't the smoothing caps charge up to a mostly DC level thus
back biasing the diodes for most of the RF cycle?

I don't keep up with this newsgroup on a daily basis, probably more like every couple weeks due to my work schedule. After reading this one though thought I'd better respond. Not sure how long ago it came in but I had a very bad experience with Texas Towers when buying a Yeasu FT 100-D. You'd think that after paying over a 1000 clams for something that you could expect better than "very" rude behavior from the salesperson. The red flag went up in my brain the first time I spoke to him, he was a little curt, but the other salesman had been so nice that I kind of pushed it to the back of my mind and figured he might be acting that way because I was a woman. Then after purchasing the radio and paying over 50 dollars to get it overnight, it didn't come in until Monday. I wanted it for the contest that weekend. I had payed $30 for over night and didn't get it. I also did not get the extra back. He flatly told me he had made one call to ups and he was not wasting anymore of his time calling again. Mind you I had just spent quite a bit of money. I told him that was a pretty bad attitude to take towards a customer and he wouldn't get anymore of my business if he wanted to act that way, his answer to me was I don't want any more of your business. Since then have had several reports from others of similar bad experiences so you might try another source for this antenna if you want one.
After that if you get it I'd love to hear from you how it works out. We have thought of buying one for similar reasons. Sorry so long, Thanks, 73' Kathy AC4LB

Cecil:

But... but...

If one places a choke balun [aka common mode choke] on those offset feeders cannot the unbalance on the feeders be eliminated and so help to correct the radiation pattern?

Initially I like the thoughts of getting a higher feedpoint impedance/resistance for an 8JK array. Even Kraus would agree that its' feedpoint impedance is dicey! One of the main problems that I have noted with closely coupled "super-gain" driven arrays such as the 8JK is the low feedpoint impedance and the consequent matching problems.

Traditionally I believe that 8JK experimenters have addressed this deficiency, among others, with lumped impedance transformers, i.e. networks or transformers/baluns...

What is being suggested here is to address the feedpoint impedance transformation issue for an 8JK array by means of a simple offset feed, analogous to how a Windom or other such is fed.

When I read it, I hit myself on the forehead, and I said, "now why didn't I think of that"?

Thoughts, comments?

Cecil:

OK, I admit it.

I don't really know what was causing the interference, but when the "in line" SWR meter was taken out of the line, magically the TV Interference went away, never to be seen again. It came back whenever the SWR meter was put back in line.

Suggestions as to the reason for the elimination of the EMI appreciated, I only guessed it was the diodes in the metering circuitry.

If the SWR meter was not properly shielded, it could leak primary
RF. If common-mode currents were present, the SWR box might have
a different radiation pattern than a piece of coax.

I didn't mean to shoot down your theory, Peter. But charging a
DC cap is not nearly as effective at TVI as frequency doubling
by rectifying only.

Richard Clark wrote:
"Further, that there is a speculation of dissipationless resistance as a physical reality, and it some how answers to the name R in this Z - THAT has not been demonstrated."

Physical reality is something we sense by sight, sound, smell, taste, touch, or something like that. Electrical impedance is sensed indirectly by its effects.

There is ample verification of large values of transmission line impedance which take little of the energy away from the total they carry. That large impedance which saps little energy is sufficient proof of "dissipationless resistance" in a transmission line. It`s not reactive because the drop it causes has the voltage and current in-phase, So, it has to be classified as a resistance, not a reactance.

Similarly, we can measure power into an antenna by I squared R, the FCC prescribed method, and note that the measured R at r-f is much greater than the d-c conductor resistance, even when this d-c resistance is incremented by the "skin effect" produced by r-f. Further, we may determine by the lack of heating that conversion of r-f to heat in the antenna is low. So, where does this resistance come from? It isn`t from reactance. In our example we will specify a resonant antenna load. The antenna resistance we measure comes from radiation which takes antenna current in-phase with the antenna voltage. Antenna resistance is dissipationless because it doesn`t heat the antenna.

Similarly, d-c can be rapidly switched on and off into a load on a 50% duty cycle. A d-c meter will display the average current. A practical application is the "dwell meter" used to measure % ignition point closure time in the Kettering ignition system for gasoline engines. The % dwell time may be quite different from 50% by design, but if the current is effectively cut in half without a resistor, no heat is produced during the 50% off-time. This is effectively another "dissipationless resistance". This same on and off switching is used when a diode is placed in series with an a-c lamp. This same mechanism is used by the reduced conduction angle of a "Class C" amplifier.

"Dissipationless resistance" is why Walter can measure a source resistance in his "Class C" amplifier which matches his load while the indicated efficiency runs around 70%. If all the output resistance of his amplifier were of the heat generating kind, his efficiency would be limited to 50%.

Best regards, Richard Harrison, KB5WZI

Gary

I know they were used in aircraft, and I've seen them come in voltages between 28VDC up to 80VDC. My concern was arcing as the wafer wiper is stepping through its positions to index the rotary coaxial switch--I'm looking for something that will take daily use over a period of 10 or 15 years without needing attention. Early ones used a wax cap with a series resistor as an arc suppressor. I was sort of fishing to see this was a long term problem, or if folks may have replaced the earlier vintage caps with more modern plastic ones. I'd also be tempted to add a solid-state device to alleviate the wear on the wiper and contact blades, but then lightning induced spikes becomes a consideration...

Let's say one has a 1/2WL dipole fed 10% from the end. What is the impedance looking into the 10% part? What is the impedance looking into the 90% part. I would suggest that one would have a lot of trouble designing a choke that will cause equal currents into those two impedances. Seems to me, the 10% part would have a very high reactance which would require a choke with a super high impedance. Ever seen a choke with 10k ohms of choking impedance?

I built my own from scratch (bit heavy), but works great. I made it a few
feet longer than the typical commercial ones and found that, even with the
extra weight to be well worth the extra effort required. I fount too, that
although a gin pole may be a simple device, it takes quite a few hours to
build.

As to the commercial one at $300. Sounds like a good deal. That is far,
far, less expensive than the Rohn unit.

I had nearly a full coil given to me. It had fallen off a truck and
crunched the outer turns. aparently they didn't want to mess with it.

I used 3/4 inch copper tubing compression fittings to MPT. Clean the
threads off one end of a barrell connector (brass) and solder in place. The
inner connector of the hard line nicely fits the connector.

I know that's not a complete description, but the connectors are simple,
cheap, and relatively easy to make.

If your soild conditions are dry, and/or neutral you can bury the plain
aluminum stuff. I had some buried for 10 years with no deterioration. If
your soild is either acedic, or alkaline...don't even think about direct
burial of the plain aluminuim...

That is about the same run I had. The only difference was I buried the plain
old aluminum jacked stuff. (Neurtal soil)

Although the 7/8" stuff is good and sometimes available pretty cheap (with
connectors), it really isn't needed for HF. It's also a bear to handle
(heavy and takes a large radius bend)
If you have to purchase connectors, the last ones I bought were something
over $80 each.

If purchasing new cable, I'd go for the LMR 400 which typically runs 59
cents a foot, has slightly less loss than 9913, uses standard PL-259
connectors, and is less prone to having water run out in the shack.

I now have five 175 foot runs (shack to top of tower).

Cecil:

Agreed...if offset far enough then the left and right side feeder impedances would present a terrific imbalance, and the choking impedance would have to be quite high to be effective.

But is that not true only if both elements of the 8JK were offset in the same physical direction? What if the offsets were in opposite directions on the elements?

Now consider... what if one was offset say 10% from the left end of one driven element, and the other was offset 10% from the right end of the other driven 8JK array element.

Now... since the feeders to the two driven 8JK elements are "paralleled" or "bridged" wouldn't the impedances from either side of the main feeder be roughly balanced and therefore not need a really demanding common mode choke?

I'm probably missing something here, probably because of the phasing, etc... but is seems that it might work.

Maybe the originator of this thread has "invented' a new super directive antenna, let's call it the, "Windom-8JK", heh, heh.

Since you are retired and I'm still working for a living, why don't you try to code this up on EZENEC and see what happens.

I have downloaded this and it works GREAT!!!! It is based on the N4UU article
in QST for December, 1984.

Thanks, Franki. Saves a lot of cut and try work.

If you want the traps to be right on, you still have to do some cut and try,
but the software gets you very close on the first go.

Paul Keinman wrote:
"How do you expect to get such attenuators when cable leakage is much more than that above audio frequencies?"

I have no equipment to sell, but here are some reasonable expectations.

My Weinschell Engineering Model 933 continuously variable attenuator has a range of 3,7 db to 120 db and can handle 1 watt between 0 and 1 GHz.

My Measurements Model 80 VHF signal generator has an output attenuator calibrated down to -128 dbm or less than 0.1 microvolt at 50 ohms. Most Motorola radios are specified to have better than 0.25 microvolt sensitivity.

I have often used the Model 80 to measure the sensitivity of VHF radios without problems of coax radiation spoiling my measurements. These receivers are often good enough to meet or beat their quieting specs. at near the .01 microvolt calibration mark without help from r-f leakage.

Richard:

This "dissipationless resistance" stuff smacks of Lewis Carol's "Turtle Soup".

Surely the good old terms "radiation resistance" or "surge resistance" or "plate resistance" or "collector resistance", etc... are sufficiently descriptive of the phenomena in question.

We all know that they are not "resistors"!

We all know that those "effects" are not caused by resistors.

We all know that they do not necessarily involve electrical energy dissipation into heat energy.

We all know that there are numerous ways in which electrical energy can be dissipated into other forms of energy.

Why introduce a "new name" for "old stuff"?

Why do you, and others, including Walter, continue this attempt, abetted by incompetent editors at the IEEE Dictionary, to confuse everyone by renaming these well known and understood phenomena as "dissipationless resistors" without any other adjectival differentiation?

My only conclusion for this unecessary distinction is related to something Lewis Carol wrote and I quote...

.....

"When I use a word", Humpty Dumpty said, in a rather scornful tone, "it means just what I choose it to mean, neither more nor less."

"The question is", said Alice, "whether you can make words mean so many different things."

"The question is", said Humpty Dumpty, "Who is to be master: - that's all."

Lewis Carol, "Alice in Wonderland - The Turtle soup"
.....

Richard my man... "you are the Master"! And so, for that matter, is Walter.

"Dissipationless Resistance", can we now, fuggedaboudit?

Hi Gary,

Coated? There's so much lead in these Tubes that they should conduct
freely (5 Lbs of lead, or so claimed in the newspaper).

When I was a youngster, my first electronics lessons were with my
hands in the back of a TV. Lesson One was about the relationship
between power, capacitance, the volt, and the Aquadag. I can attest
to several successful measurements of physical heat as a result of
decelerating the stored charge of several thousand volts. No
instrumentation was used or was necessary to confirm dissipation. I
also learned my first lesson in phase shift and an RC circuit. I also
came to understand how VERRRY long one time constant can be after
turning off a TV.

Then the Navy trained me to keep one hand behind my back and the
dissipation went away - or perhaps I should say my dissipation turned
to other activities....

Hi Richard,

That is a rather nebulous statement.

> large values of transmission line
>impedance
High Z

>take little of the energy away from the total they
>carry.
low loss

>is sufficient proof
>of "dissipationless resistance"

What is an example of good engineering practices now becomes the proof
of an artificial concept? To what end? To then turn around and
decree the artificial is now real?

Lacking is the context of
>There is ample verification
In what field? Power Transmission across the grid, or my 100W down
the RG-8?

I can verify that if I put 100W into RG-8 and find it coming out the
other end, that yes, I live a charmed life with a lossless line. If I
look backward into that source of 100W and observe that there was more
available, and there was heat loss; then I must resign myself to life
that is less charmed and more real.

3783. Re: Internal Ant. Tuner with External SWR Meter???

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-24 17:58:29 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <978sq2fdc1@plutonium.btinternet.com>
Source record: 169657

Yes, I do feel the need the need to glance occasionally at a meter and be reassured all is OK as the needle bounces about. I can live with a small amount of Electromagnetic Incompatibility. And I have no desire to decry the importance of the standing wave ratio on transmission lines.

But the most insidious thing about an SWR meter is its name. The confusion and misunderstandings suffered by novices, as their experienced friends attempt mostly unsuccessfully to explain in terms of SWR the how and why of radio, could be eliminated just by renaming it.

The instrument actually responds to and indicates the magnitude of the reflection coefficient with respect to 50-ohms. It can be calibrated with a linear scale from 0 to 1. It provides a very useful measure of the departure from the Standard 50 ohms of the load presented to the transmitter. There's no need to confuse matters by mentioning the SWR on a non-existent line between the meter and the transmitter. It means very little unless that line is at least 1/4-waveelngth long and is also a 50-ohm line.

It is a Reflection Coefficient = RC meter.

Actually, a reflected power meter is all one really needs. We
generally know the generated power assuming foldback is avoided.
Seems all we need to do is minimize the absolute value of the
reflected power (referenced to 50 ohms). My 'SWR meter' reads
forward and reflected power referenced to 50 ohms. The SWR
scale on the meter is an afterthought.

I have used NMO for years with no problems. Our police mobile radios
all use NMO mounts. I had an impact with a piece of ply wood that
came off a truck in front of me on a Larson 2-70 base loaded whip six
or seven years ago. It broke the antenna off at the NMO mount, and
bent the sheet metal around the mount, but the mount was not damaged.
I screwed another antenna on it and bent the sheet metal back as best
as I could. I am still using the same mount on the same vehicle with
no problems.

Hummmm, I don't think it would be too serious. Not against a butternut anyway for all band use. For 80m only, as this antenna is sold, I'd rather run a butternut HF2V. I guess the HFV1 could do ok, but it will still need radials for each band used, and performance on the higher bands could be funky due to the long electrical length. Would be much like tuning my 40m mobile on 15m. Sure , it will work, but my resonant 15m antenna is better. Then for the low bands you have to think about the lossy helical winding compared to a lumped coil. For an all band vertical, I'd want to go with the butternut HF6V-HF9V. For a low band vertical 160,80,40 etc, I'd use a HF2V."with the top loading wires if used on 160m" For a high band vertical 20-10 I'd prefer a half wave design such as an R7 etc. In my lowly opinion, these are the best of each type that are made commercially. Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.misc

Thanks for the heads up!

Such boorish sales people, I am afraid, can set me off pretty badly. That just happens to be one of the "buttons" that *can* set me off. I once called a local attorney's office looking for my own attorney. Instead, I got a particularly grouchy old buzzard who was, in the absence of my normal lawyer, filling in--and VERY unhappy about it. Upon asking very politely some questions, I felt I was under assault by a boar HOG! He was VERY rude, condescending, and even took a threatening tone with me as if he was quite put out because I disturbed his nap(?). I asked him, "Sir, are you having a bad day?", to which it sounded like I was assailed by a junk yard dog--ARF, ARF, ARF, WOOF, GROWL!!!

I hung up the phone and I felt it start. A feeling that begins almost in my feet and, like Old Faithful, rises to the top of my head! I was shaking like a leaf! Not from fear, but from RAGE! I grabbed my jacket and made for the car. I drove uptown and parked the car, then went into the offices of these attorneys. I was still mad, but not like I was at first. But I walked right into the old geezer's office, brushing past the secretary and I pointed my finger right in that old SOB's face and told him this: "Mr. Whitesides, if you worked for my corporation and even looked like you were going to talk to a customer the way you just got thru talking to me, you'd be out on your keister within the hour! Next, if you EVER, EVER talk to me like that again, you old buzzard, you had better file a flight plan because you WILL go on a short TRIP. I WILL bust you right in the mouth and send you skidding across the floor! You have an alligator mouth and a canary a**, and you're fixin' to write a check that canary a** can't cash!"

The old guy was rigid against the back of his leather office chair, knuckles whitely gripping the arms. I scared the dickens out of him! All during this diatribe, all he coud say was, "WHA--, WHA--, WHA--!" I also reported him to the local bar association which put a black mark on his record.

Now that WAS an ugly exchange that I probably shouldn't have engaged in. But. you know, that lawyer has been exceptionally nice to me ever since! LOL!

Best,

Jerry

Hi Gary,

Yes, your point above is well taken. I was rather too focused at the
atomic level. The lack of heat is more a matter of an efficient
conversion to shorter wavelengths in the phosphor's atomic resonance.

Hewlett Packard, a premier LED (another source of cold light)
developer, has recently achieved one of the highest efficient
conversion rates of 55% (well perhaps I should modify to a source of
lukewarm light). Just can't seem to shake that pesky matching
condition!

> Antenna resistance is
>dissipationless because it doesn`t heat the antenna.

Hi Richard,

This is simply the perversion of language to abrogate the meaning of dissipation. Newtonian Mechanics holds original claim, in the field of science, to the intent and meaning of the word dissipation.

To quote Feynman on "12-2 Friction" :
"the mechanism of power loss ... generate waves and atomic motions and, after a while, heat...."

Classically, in the Newtonian Mechanics we all so dearly hold to, heat is an unrecoverable loss of energy. The source having once expended the energy cannot acquire any part of it back. (I won't quote Feynman on Carnot.) This goes to first class in freshman physics where we observe that a sliding block that encounters friction loses power to heat THAT being a form of energy, is in a state of imbalance, flows toward a cooler mass and thus DISSIPATES the energy by spreading it out of recoverable reach across a growing radius as long as there is a temperature gradient. ...then we get into entropy.

Do we speculate about the existence of a non-entropic resistance?

Dissipation means unrecoverable.

HEAT is an unrecoverable loss of energy.

Radiation is an unrecoverable loss of energy (for the same reason).

Radiation HEATs anything it illuminates IF what it illuminates can absorb the wavelength of the radiation. The simple proof of absorbtion is found in the deceleration of a charge and the rise in temperature.

HEAT in turn Radiates any region cooler than it.

There is absolutely no difference in physics between the radiation of HEAT and the radiation of your signal.

These HEAT appealed arguments forget that HEAT is not a physical entity! It is a state of perception arrived at through sensation. Throughout the Universe there is a continuum of temperature, for which there is very small band of thermal activity where we smugly reside

and arrogantly create an island of physics called HEAT. Each and every step wholly subjective and fully impossible to accurately describe. If you simply accepted the bare math and dismiss this subjective snuggly warm term of HEAT then all the logic of dissipationlessness would collapse.

Richard Clark wrote:
"That is a rather nebulous statement." Richard Clark suggests large values of transmission line impedance are simply "High Z". That is a good simplification. I should have said that characteristic impedance is usually much larger than line loss resistance.
Richard Clark also suggested that High Z which takes away little of the energy from the total carried is simply "low loss". Again, a good simplification.

Richard Clark also wrote:
"Lacking is the context of: There is ample verification."

It is self-evident to me that a high characteristic resistance that eats no energy is lossless, though it is High Z by comparison with copper resistance in the transmission line. This is true for the Electric Company`s line and for Richard Clark`s RG-8.

I beat around the bush with "large values of transmission line impedance" because I didn`t want to call RG-8 High Z cable. Next time I`ll try to clarify with fewer, shorter words.

Hi John,

Thank you, yes, helical resonators. My reference is "Reference Data
for Radio Engineers," Chapter. 22 Transmission lines.

If you wanted to optimize the Q of the coil (this is largely the only
structure if you don't count the walls) there are nomographs for any
consideration.

I will simply use the already illustrated exercise found in the book.
We have a 30 turn inductor for resonance at 10 MHz. The unloaded Q is
the desired engineering goal (or marketing goal, what have you...) and
for this example is idling at 1000.

To fulfill the expectations of the preceding paragraph we come up with
that we need a 30 turn 3 inch diameter coil inside a 6 inch diameter
can. To obtain the unloaded Q of 1000 the turns pitch needs to be
0.16 inch.

The geometry of this clearly reveals that the turn to turn capacitance
is much more dominant (by nearly 10:1). However:
"It operates as a distributed-parameter system equivalent to a
quarter wave co axial transmission line resonator."

This quote becomes obvious when the coil unwinds to maximize Q with a straight wire in a coaxial, quarter wave length cavity.

Let's examine that defining tenet recently expressed:
>Its an old wives' tale that Q is poor when most of the capacitance is of the >parasitic variety.

A straight wire is nature's way of minimizing parasitic capacitance.

Hi Guys,

Sounds like an open ground (in a secondary path) to me. You'd be
lucky to get harmonic components of more than 1 mW out of them. And
the only way to support that meager power would be in a resonant (at
the freq of the RFI) structure - presumably your antenna this meter is
connected to. That puts this 1 mW very distant from the house (I
presume) and least likely as a specific source of that RFI. The
general source being the meter assembly is obvious.

Is this a remote reading head SWR Meter?

Richard Clark wrote:
"This is simply a perversion of the language to abrogate the meaning of dissipation."

Good! So now I`m a pervert!

We distinguish between radiation resistance and loss resistance in an antenna. Dispersion of radio energy is not called dissipation. Conversion of radio energy to heat by antenna inefficiency is called dissipation.

Energy eventually degrades to heat we can`t use. It isn`t hot enough to do us any good. The unavailability of energy to be used is inevitably increasing and thus it seems the entropy of the universe grows.

Richard Clark also wrote;
"Heat in turn Radiates any region cooler than it."

Didn`t keep my thermodynamics books but my recollection is that all warm bodies radiate heat according to their temperatures and exchange heat energy with surrounding bodies and space. A hotter body transmits more heat to a cooler body than it receives from the cooler body.

Such attenuators do exist. I have in the shack a 0-100 dB
attenuator in 1 dB steps. It was manufactured by Pascall, UK, about
5 years back. I forget the price but it was quite expensive. Don't
know whether the firm still exists. Built into a solid die-cast
aluminium-alloy box.

Cable leakage does not increase with frequency - it decreases.
Worst of all at DC and audio frequencies. Leakage occurs mostly at
connectors. Use threaded types, not simple plug and socket.
Impedance mismatch at connectors is no problem with attenuation
measurements.

I have made measurements up to 160 dB at up to 5 MHz by comparison
with variable attenuators. A 10 watt signal generator is needed.
Without any extraordinary precautions it is possible to make
measurements with an uncertainty of a few tenths of a decibel at
100 dB.

I have also made measurements with a precision of 0.001 decibels at
frequencies up to 10 MHz. Such measurements are necessary to
determining the loss vs temperature coefficients of components and
systems when it is possible to vary the temperature only a few
degrees C. A high precision is also needed when calibrating field
attenuators against laboratory standards.

Jack is half right, but based on my experience with the discpole, the job isn't impossible or even difficult at HF and VHF frequencies. As a practival rule, I've found wound choke baluns work a lot better than beads or sleeves. I don't know what Cecil said, but I wouldn't make the blanket statement that you can't cool out the feedline of a OFC because I regularly accomplish this. I DO know a coaxial choke is the only thing that has worked well for me. None of the solutions that depend on a balanced feedpoint performed successfully.

I'm considering a Comet/Maldol MH-209SMA antenna for my Yaesu FT-50. The short length would be nice for stuffing the radio in the small bag under my bicycle seat or in a jacket pocket when snowmobiling. The original antenna got damaged beyond repair doing these things and the Comet SMA-503 that I bought as a replacement is getting bent too often near its base, although it performs very well. I'm lucky to live and play near the local repeaters so I really don't need a long range antenna, just a rugged one. I like the idea of the MH-209SMA being short and flexible. Has anybody tried one?

Reg:

Agreed.

Actually most of the "cheap" so called SWR meters really only indicate a "reflected voltage" [with respect to a 50 Ohm reference resistance] and not the reflection coefficient. Since the reflection coefficient is defined to be a ratio of two voltages, that is the reflection coefficient is the ratio of the reflected voltage to the incident voltage, but the meters usually only sense and indicate a version of the reflected voltage, they do not really compute the ratio.

It would be nice to have such instruments with a built in capability so that one could adjust and set up a reference impedance and could measure reflected voltages with respect to an arbitrary reference impedance say Zr instead of a 50 Ohm resistor.

In my non-HF work I have often needed such an instrument and had to build my own from time to time.

For instance in wire line transmission engineering in telephone plant, we encounter cases of very long lines at low frequencies, the transmission line "surge impedance" may be complex and actually vary over an order of magnitude throughout the band of interest.

Cecil:

I like those "cross needle" beauties... they indicate the SWR at the point where two needles cross, as well as incident and reflected voltages and display it all simultaneously!

Cross needle SWR meter... one of the neatest ideas I've seen, just wish I'd have thought of that concept.

Proves once again the oft forgotten superiority of analog computation over digital... that's why I "pine" for my old log log slide rule.

Dick:

I have a couple of those Drake meters. The Drake meters have their scales marked in Watts, but they are not measuring watts, an examination of their circuitry reveals that they measure only reflected and/or incident voltages, not power.

If the impedance they work into/with is fixed at 50 Ohms resitive then they give a close indication of the correct power because in that case power will be proportional to the square of the voltage. But if the impedance is off 50 Ohms resistive, the power indication on those scales is not accurate!

To measure watts, the meters would have to measure both voltage and current simultaneously and multiply them together to get to watts. Or... like the "bolometer" measure the power by measuring the heat in a resistance or some other such technique.

I guess that it must be quite expensive if you really get such
accuracy as you later claim, even in a controlled constant
temperature.

I also suspect that the VHF/UHF performance is not that spectacular
and since the original poster did not specify the required frequency
range, I originally asked about it.

>Cable leakage does not increase with frequency - it decreases.
>Worst of all at DC and audio frequencies. Leakage occurs mostly at
>connectors. Use threaded types, not simple plug and socket.

DC and audio circuits generally have a much higher impedance levels
than 50 or 75 ohms used in RF circuits, so the capacitive coupling is
a much worse problem. At very low frequencies the coaxial cable does
not work properly as a transmission line, thus the isolation is not
very good. However, due to losses at very high frequencies, the shield
no longer act as a perfect conductor and you can get different
currents flowing on the inside and outside of the shield.

>I have also made measurements with a precision of 0.001 decibels at
>frequencies up to 10 MHz.

I guess that must be the readout resolution in some comparative
measurements but not an actual precision. A 0.001 dB voltage ratio is
115 ppm (0.015 %), so I wonder how this accuracy could be maintained,
especially if some real power levels are involved heating the
attenuator.

Oh! blow, Actually I attended Whitefriars when the Galss works was still operating there. I think that most if not all of their glass was lead glass. I had done w bit of glass blowing with that soda glass that one could get from Timothy White's and it was very forgiving. Then I tried a bit of the lead glass and all I got was a scaley black mass. I guess I need lessons. Still for the stuff that I'd like to do lead glass would probably not be ideal.
I didn't know that lead glass conducted electricity. I suppose tey use lead to decrease the effects of long wavelength X-Rays off big colour tubes.

> When I was a youngster, my first electronics lessons were with my
> hands in the back of a TV.

I did a few of those, old 405 machines before I went into the mob. self taught I even made my own components, much to the amazement of a friend who had done his National Service in a Radio trade, he said that they had never taught him to do anything like that. When my turn came I found just how true that was.

>Lesson One was about the relationship between power, capacitance,
>the volt, and the Aquadag.

And the backed on dust coating that turns into conductive carbon and leaks away all of the EHT once it goes really solid. Just cleaning that coating off and applying some fresh Vasaline acround the tube connection, and a good clean of the screen inside the safety glass increased the apparenr brightness of an old set sufficient to get a few bob off the owner. What did annoy me was supplying parts and not getting paid for them, and of course in those day the other trap of fixing a fault in the line circuit and a month later the frame circuit fails and you get the whinging "What have you done to may set" syndrom, or the knock on the door just as you wee sitting down to Christmas dinner, my sets playing up can you come and look at it we want to see the Queen's speech. After I married The Dragon would chase such calls away. Still in those days every suite and sports jacket had money in it.

> I can attest to several successful measurements of physical heat as a
result of
> decelerating the stored charge of several thousand volts.

My most unfavourite way of discovering heat was the unmistakeable odour of wool burning. Those leather patches on the elbows had their uses when Solons were around.

> No instrumentation was used or was necessary to confirm dissipation.
> I also learned my first lesson in phase shift and an RC circuit.

And also the 6 dB per octave frequency penalty for RC coupling, and the integrating and diferentiating qualities of those early flywheel timebase sync seperators.

> I also came to understand how VERRRY long one time constant can be
> after turning off a TV.

So did I till I discovered the crock clip long wire and resistor.
Of course a faulty earth connection to the aqua dag coating was another trap.
You could also get quite a nasty nip off the scan coils.
You weren't a tradesman until you'd had a belt or two.
RF burns were another thing, I didn't like the smell much, I smell a bit like chicken, pity really cos my missus thinks I'm a pig or is it an old bore. (sic)

> Then the Navy trained me to keep one hand behind my back and the
> dissipation went away - or perhaps I should say my dissipation turned
> to other activities....

The RAF trained me to keep one hand in my pocket,
since I left the air force I don't bother; can't get it in
the Government always have their hand in my pocket instead.

Yes, the service also trained me in various forms of dissipation, smoking, drinking, and filthy women. But I have never used drugs and don't intend to start when I see first hand what it does for those that do.
Well that's taxed yer brains enough for this session,
I'll be getting to OT brigade going in a minute.

Apart from noise considerations the only other matter is of course
efficiency, we don't see enough of it recognized directly in the topics in
this group. If it crops up at all it is usually in another guise.

> Hewlett Packard, a premier LED (another source of cold light)

55% that's beginning to be promising, when they get above 80% we'll perhaps
have some confidence that they know what they are doing.
I guess then they'll be going into the lightbulb business in the interests
of ecology.

What incidentally is the light efficiency of the old filament lamp?

Stray capacitance of a solenoid is the sum of two components. Their relative contributions depend on the number of turns.

The strays can be lumped together to form an equivalent capacitance in parallel with the coil's inductance at the natural self-resonant frequency. Depending on an isolated coil's length/diameter ratio, the strays can also be considered to be uniformly distributed along the length of the coil which then behaves as 1/2-wave transmission line at its self resonant frequency.

The principal component can crudely be decribed as the capacitance between the two half-cylinders when the coil is cut at its center. The electrostic field spreads out into the surrounding space in a manner similar to the magnetic lines of force around a bar magnet.

The other component is due to capacitance between turns. With a single turn, as in a magloop, the between-turn capacitance is obviously zero. With two turns the capacitance in shunt with the the coil is a maximum. The two components are one and the same.

But with N turns the equivalent parallel capacitance is only 1/Nth of the capacitance between adjacent turns because the individual capcitances are all in series with each other. So as coil length and N increase, the first component rapidly predominates.

In any case, if the insulating material between turns is of high quality, even with only two turns, turn-to-turn capacitance will not degrade Q any more than any other sort of circuit component.

When a helical resonator is enclosed in a screen it increases capacitance somewhat and distributes it more uniformly along its length. But the screen does NOT increase coil Q - it merely maintains the natural high Q of the coil it by preventing the external field from interacting with poor uncontrolled dielectric materials and lossy conductors in the immediate vicinity.

It is the interaction of a coil with its environment which makes the working Q of a tuned circuit less than that which may be calculated on the assumption that the coil is isolated in space. Q meters are part of the environment !

Peter, the division sum is performed by the moving coil meter scale. It follows from the method of calibration. The meter reads a FRACTION of full scale.

Meter calibration could not be more simple : open circuit or short circuit the antenna side of the RC meter and set meter sensitivity for full-scale deflection = RC = Unity.

It is, of course, the magnitude of RC. It gives no indication of phase angle. I think your desire for indications relative to a whole range of reference impedances can be satisfied only by a complex impedance bridge and a built-in computer. Even the MFJ-259B cannot tell you the vitally-important sign of the phase angle.

Absolute accuracy should not be confused with precision.

To measure attenuation within "a few tenths of a dB" (at any attenuation level) entails detecting a difference between two voltages which are a few percent different from each other. This is an easy job for any voltmeter. Errors are not due to the comparing voltmeter but to the measuring components, cables, connectors and layout.

Accuracy entails comparison with a local standard. There will be uncertainty in the local standard in addition to errors introduced during the comparison process. There will also be uncertainties introduced at each calibration level up to the International standard.

Precision is related only to local effects such as signal to noise ratios. It is relatively easy to detect a difference of 10 microvolts between two voltages of about 1 volt each. This corresponds to a precision better than +/- 0.0001 dB

A wattmeter needs a phase angle. Are you sure they don't sample current
and voltage and add/subtract them vectorally? My wattmeter obtains a
sample of current with a toroid and that sample is in volts. It also
uses a capacitive divider to obtain a sample of volts. It assumes it
is in a 50 ohm circuit and vectorally adds those two values to get
forward power and vectorally subtracts those two values to get
reflected power. The vector addition/subtraction takes care of
the phase angle.

3825. Help with possible new antenna set-up

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-25 14:22:12 UTC
From: "Tracy L. Brooks" <rescue@wilkes.net>
Message-ID: <97b4ne$6lfo$1@news3.infoave.net>
Source record: 169599

Greetings all,

I'm thinking about making a new (used) multi-functioning tower for my
new house.
If anyone can offer advise, I'd be most appreciated.

This antenna will be used mainly (90% +) for receive. It may be however
be used
for tranmitting in the future.

The specs are as follows:

Tower height: at least 40 ft.
Distance from house to bottom of tower: approx. 300 ft.
Frequencies (devices) on tower:
1- VHF hi band antenna (tx and rx) (Public safety and business
bands)
1- UHF antenna (tx and rx) (Public safety and business bands)
1- 800 antenna (tx and rx)
1- conventional TV antenna (for local TV stations)
1- Mini dish satellite antenna (Dish 500)

Reason: My home is in a hole and I would like the antennas to be at the
highest spot on my
property. I was interested in finding out what type of coax would best be
suited for running
such long lenths. Also, should I separate the coax into different conduits
or will they
all work in one? One more thing: I don't have the tower yet, I would
prefer a free standing
tower but a guidewire will work. Where is the best place to find used ones?

Thanks for any help,

Tracy L. Brooks,
rescue@wilkes.net

3826. Another theory question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-25 14:39:05 UTC
From: Bill Manley <b_manley@bellsouth.net>
Message-ID: <BO8m6.9560$4f.19625920@news1.mia>
Source record: 169600

Noting the interest in the "Warner was right .." and "question on theory" threads the group might enjoy entertaining the following question which was offered to me in a job interview many years ago.

Given two equal capacitors (C1 and C2) arranged in parallel but separated by a normally open switch. With the switch open C1 is charged to voltage (V). C2 has no charge. Also given is that all circuitry is lossless. Then the switch is closed.

Before the closure note that the energy in the circuit is

Ebefore = C1 * (V^2) / 2 + 0

After the switch is closed, the charge Q is equally shared by both capacitors. The voltage on each capacitor is now V/2.

Now the total energy is

Eafter = C1 * (V^2) / 4

Where did the energy go?

(BTW, I did get the job)

regards,

Bill Manley KB4XE

Thanks for the advice! The Arrow J-pole is looking better and better:

-- should be easy to waterproof
-- no passengers impaled on radials
-- many options for homebrew mountings
-- the price is right!

If I have any particularly good or bad experiences, I'll post them.

Thanks again!

JT (KB6WIJ/5)

Use your 156.8 MHz with an A-B antenna switch.
SWR is under 2:1 and my 2M FT2500 loads just fine...

Conversely, if you come up with a hot 2M antenna, use it with your marine band
VHF radio...

>
>Best regards, Richard Harrison, KB5WZI

Hi Richard,

Your cooler body, presumably shy of absolute zero, adequately fulfills the spirit of my statement.

However, we agree that HEAT radiates as easily as RF.

Now, if I were to load up into my dummy load - a complete conversion to heat - Energy would still be radiated, and it too would be unrecoverable by the source of this emission.

Now we have an infinite line, actually any line, a resistor, an antenna, all dissipating energy (and so will a tank).

Again Dissipate, as a technical term, reaches further back than one century. Per the Oxford English Dictionary, one usage (and the principle entry for this word) dates to 1532:
"To scatter, to cause to go off in all directions; to disperse...."

Well, what about Dissipation (given we have dissipationless)? The OED has an entry on that (of course, it has 750,000 entries) from 1615:
"The wasting of a substance, or form of energy, through continuous dispersion...."

Radiation weighs in from 1812 with:
"The manner in which the energy of a vibrating body is transmitted in all directions by a surrounding medium; the emission and diffusion of heat rays; the process by which heat passes from a heated body...."

And lest we forget, your BEST antenna for your largest audience wasted more than 99% of the power applied to it, in getting that power to its load. And what is worse, the load had to amplify your power (and thus

driving the efficiency further into the toilet) to make your power useful! Your antennas could've fallen to the ground half way through your broadcast and efficiency of power transfer wouldn't have changed more than a percent. Now tell me about loss in the rivets as compared to the call of free space. :-)

If there were a prize for gold plating resistors, then Hams would have more blue ribbons than qsl cards. An antenna represents the one good resistor in our tool box, and to purify it, return its sanctity so to speak; we cannot say that it dissipates as it did faithfully for centuries in the past.

As for:
>Good! So now I`m a pervert!

Not yet, my lotus eater - you have yet some time to learn from the master.

Hello Everyone,

I have been searching for the specs of the 2m 4 element Pounder
Antenna that was published in the ARRL magazine, a while back.
I have not been successfull in locating information on this!

Does anyone have the specs and building information for this?

If you can pass it onto me, it would be greatly appreciated.

Thanks,

Next time you are on the road, look at the lorry tail lighs. There's
a better than 50% chance they are LEDs! Europe is running at about
66% and the US about 40%.

Take a look at the control lights at the intersection. Same there
too. LEDs can pay for themselves in one year of use, and last 10
times longer (at that higher efficiency).

You know, you may want to try building a J-Pole Antenna.

They fit nicely in the attic, and they are small enough to fit
verticaly.

Yes, spider antennas are multi-band, designed for any 4 bands, with no need to swap coils. I put a second ring on mine about a foot below the top one and put three more resonators so I can go mobile INSTANTLY changing bands between 10, 12, 15,17, 20 , 30, and 40. As I am almost 100 % mobile CW, I just tune them to the middle of the CW portion and never have to tune again. If I do decide to go SSB, I just use the internal tuner on my TS440sat. No, it won't outperform the Texas bug catchers or screwdrivers, but I don't have to take my eyes off the road or get out of the car to tune each band.

But 7-band spiders are for real hams, not wimps, as you will get plenty of stares at your upside down Christmas tree! :-) If you don't mind that, and guy it well, it should last you for many years.

>
>Paul OH3LWR
>

Hi Paul,

Precision, Resolution. These can be the same thing or different;
however neither are a statement of accuracy.

When my old Drake TR-7 VFO gets buggy, I might note some one at
47.1652 MHz and smile at the precision of that reading, and yet it is
off by 40 MHz (an errant 4 is showing). Lots of precision, lots of
error.

However, as your question lies dormant:
> I wonder how this accuracy could be maintained,
>especially if some real power levels are involved heating the
>attenuator.
which is a concern shared by any metrologist. The load is the
defining point of a power measurement. The load must be known and
with power applied - it changes.

The first, and simplest, solution is to over engineer the load's
ability to "DISSIPATE" energy. (sorry to scream in your ear, but
others here needed to hear that) That would suggest using a 100W
continuous service Dummy Load to measure 10W period limited power
measurements. Or simply measure the load under the power applied.

Attenuators, on the other hand, are not 100W and few are 10W devices.
Most are on the order of 0.1-5W. So, I presume you wonder how to get
one of these into the signal path of a 100W rig? You use a
directional coupler to tap a portion of the power (and you need to
know the portion, but accurate determinations are fairly simple) and

feed that tap through the attenuator and add the coupling loss (or that portion) to make a total.

In short, you have a 100W Source, a 100W Load, a 20 dB Directional coupler, a variable attenuator, an attenuator Load (how many miss this one?) and a detector. You can now read applied power at a 1W level instead of the 100W level. And you can measure the variation from that level with reference to your 100W reading to the resolution of the detector. Resolution or precision could run quite high. A measurements of change would also find high "relative" accuracy.

Relative accuracy means you do not need to know where you are, or where you started in absolute terms, merely how far apart they are. There is an interesting implication here in this subject. As we are interested in attenuation, any measurement of an attenuator is both "relatively" and "absolutely" accurate. This is one of Gary Peach's link pins to the absolute measure of received power.

I was thinking about using a mobile whip antenna for vacation use. It would be used as a base station antenna. It wouldn't be mounted on a car or rv or suv. Its important points would be that it gets out, and it is portable.

1. What is a source of instructions for contructing one homebrew?
2. With the conditions I described above, what kind of ground system would I need?

Thanks and 73,
KB2AMY

Use an SO-239 - 3/8x24 adapter with a mirror-mount bracket and put it on a short piece of mast. On the base of the bracket, put 4 pieces of speaker wire as long as you can get. When you get somewhere, attach the piece of mast to something and uncoil the wire as much as you can.

Personally, I think you'd do better with a simple dipole.

Source record: 169614

I am looking for an antenna to attach to a few antique and 1960 era radios. I listen to these radios on AM/FM/ and SW bands. I have been told to just run a long wire on the roof, but there is not a good location for this wire without my wife making an issue of it. Is there another solution? I have seen comments about wide band vertical antennas. Will this work and if so which ones do you recommend and where would I purchase it?

Thanks for any help
Mike

3842. Finally put some of that old ethernet cable to work

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-25 22:03:04 UTC
From: Robert Casey <wa2ise@ix.netcom.com>
Message-ID: <3A998118.D3212BA0@ix.netcom.com>
Source record: 169615

Had some ethernet cable from the old computer days. Stuff is equivalent

to foam RG8U, with lots of shielding. Put it to work on my attic HF dipole
antenna, replacing some RG58. Of course the SWR got worse, but that's the less lossyness of the ethernet doing that. I varied the feedline length to
get my TS440S automatic tuner to tune everything except 10 meters.

I don't think any MIS people use thick ethernet anymore for computer work. Presense of vampire tap holes doesn't seem to matter much at HF.

3843. Antenna Switch.

We've done this one before on the newsgroup -- or maybe it was
rec.radio.amateur.homebrew.

Connect the capacitors with any finite resistance. It's easy to show
that the "missing" energy is dissipated in the resistance. In the limit
as the resistance goes to zero, the current increases to an infinite
amount. However, you'll find that the integral of I^2 * R remains
constant, and always equals the "missing" energy.

Roy Lewallen, W7EL

(A variation of that question was also on my P.E. exam.)

One thing that wasn't mentiond from the first poster, look around your neighborhood and see where everyone else is pointing their antennas, and the size of the antennas. Does your antenna look like theirs? Has it worked in the past in that location or is it something you just put up? If it worked in the past, the feedline or antenna could have degraded and needs replacing. Try troubble shooting it and do the steps Bill mentioned. If it is a new installation, read the first 2 lines again.

Dear Group,

I am in need of some assistance. First, let me describe what I currently have, what I am planning to get and then the two questions.

Current installation 2m/440 radio wired to battery with magmaount dual-band antenna on roof fed with RG-8X/PL259 through rear barn door (double doors hinged on the side).

I am getting some water leaks (surprise, surprise) after several months of no problem.

Future radio I am planning on upgrading to HF with an FT-100.

Question #1: Is there anyone who makes a magmount that uses a few feet of the very thin RG-188 and will that prevent the water coming on or is any cable coming through a door going to distort the water seal enough that water wickes past it?

Question #2: If I have to drill holes into the car (which I don't mind), should I wait until I get the HF radio and drill one hole for a combo antenna or would it be better to have one antenna for 2m/70cm and another one for HF (I.e. drill now and add another hole later).

Question #2a: What's a recommended

Jeffery,
In order;
1. No. Anything breaking the seal at the door is going to leak.
2. Why not wait till you know exactly what you want to do. Saves 'extra' holes. Personally, I'd use seperate antennas.
2A. That depends. How many bands? How many 'moves' on the same band? Will you change freq/bands very often? What kind of power levels are you anticipating using? How much are you planning/willing to spend?? The efficiency of mobile antennas is directly proportional to it's 'ugliness'... how much 'ugly' can you stand?

'Doc

Never was a more true word spoken. Lots more job satisfaction too.

To find size of tuning capacitor needed to tune over a given
frequency range for a given size loop, download in a few seconds
program MAGLOOP4 from website below. Not zipped up. Run
immediately. Compare performance between one shape and size and
another.

Construct loop from standard sizes of copper water pipe and angles.
Can be any regular shape from square to octagonal. Use your
imagination for construction details and fitting the tuning
capacitor.

Bill, KB4XE wrote:
"Where did the energy go?"

Connecting an uncharged capacitor in parallel with an identical charged capacitor leaves each of the capacitors with half of the charge and half of the original voltage of the first charged capacitor.

Nothing has been lost. The same excess charges exist in the capacitors. The paralleled capacitors can be reconnected in series to restore the original voltage across the single capacitor.

OK, here is my progress report.
I put the 80 and 40 meter Isotrons together last week and did the initial tuning with an MFJ-259B. Pretty easy to do with a short co-ax jumper I could make adjustments from my chair. I should mention that the antennas are mounted back to back on a 5 foot mast section held by a roof top tripod and standing in my dining room. I adjusted each antenna before connecting the co-ax tee and the cable to my transceiver (FT-847). I was able to adjust my MFJ antenna tuner on 40 without much trouble and made several contacts in Europe. According to the meters in the transceiver and the tuner I was getting full output. I could not seem to tune the 80 meter band though. This weekend I set up the 20/15/10 meter antennas on another mast and tripod. These have twinlead jumpers connecting all three and the co-ax feeds the 15 meter antenna. After tuning them seperatly with the 259 I finished hooking them up and tried to find the "sweet spots" on each band. Not much luck. I finally got smart and hooked the 259 up -through- the tuner. I set the center frequency of each band on the 259 and adjusted the tuner for the lowest swr. I got under 2:1 on each band and wrote the settings down for quick reference. No wonder I couldn't find the setting for 80 meters without the 259! It's -very- narrow. But I get 1.1:1 when properly tuned in. Since I found the settings I have been able to tune by ear on the receiver noise when changing frequencies. So, using the antenna switch on the tuner to select which antenna stack I'm using and tweeking the tuner for best swr I am able to work on 80, 40, 20, 15, and 10 meters. I have a 6 meter halo that will go up soon and a Cushcraft AR-270 for 2 meters and 440. I did have to buy a duplexer for that one. I was able to complete a schedule with my friend Ron WA9QNN in Grantsburg for the first time (on 40 meters) this weekend.
The Isotrons have tuning stubbs or counterpoises built in and require no ground to work. Good thing as I am living in a second floor condo with no outside antennas allowed.
Am I happy with the Isotrons? You bet. I might even get the 160 meter and the 30, 17, and 12. That might cause a problem though as the 30 meter is meant to go on with the 80 meter instead of the 40. The 17 and 12 are very similar to the 20 and 10. If the 80 is so narrow I'll bet the 160 is super narrow. You have to expect that trying to use such small antennas on the low bands but it does work.
Well that's all for now. 73 Gary N9ZSV

Hi Bill:

The energy (time integral of power) did not "go" anywhere. Since there are no losses and there is no radiation, the total energy in the circuit "after" must equal the total energy in the circuit "before". Your equation for total energy after, Eafter, is simply incorrect.

Energy in a capacitor is the integral of power as a function of time. Power is a scalar quantity, a function of voltage and current, which are both vectors (complex). Power is equal to |V| |I| Cos (A), where A is the phase

angle delta between voltage and current. The direct addition of energy and power cannot be performed in the manner you describe because scalar additon does not contain the phase relationship information between E1 and E2 (they are in phase) which is needed to "add" them. As a result, energy and power do not "add" algebraically, ie, Etotal is not equal to E1 + E2 (this seems to be a hard concept for some to understand).

The total energy in the circuit before, Ebefore is equal to C1 * (V^2) / 2

The total energy in the circuit after, Eafter is not equal to C1 * (V^2) / 4.

If the energy in C1 is equal to E1 and the energy in C2 is equal to E2, the total energy in the circuit is given as follows:

Eafter = E1 + E2 + 2 Sqrt(E1) Sqrt (E2) = (Sqrt(E1) + Sqrt(E2))^2

Eafter = C1 * (V^2)/8 + C2 * (V^2)/8 + 2 * [Sqrt(C1) V / Sqrt(8)] [Sqrt(C2) V / Sqrt(8)]

Since C2 = C1

Eafter = C1 * (V^2) / 4 + C1 * (V^2) / 4

Eafter = C1 * (V^2) / 2

The law of conservation of energy holds.

Hello,
I am not an expert on antenna design. I want to make a tiny transmitter for the European 868 MHz band (license free short range devices). The antenna must be on the PCB. I have a 433 MHz example from Linx Technologies. It is rectangular (28 x 13 mm) and has a 50 Ohm impedance. Are there any good references on this kind of antennas or is there a software program to calculate the required dimensions. The antenna must be small and may be inefficient; transmitting power is about 0 dBm, I need only 10 meters range.
Thanks,
Reinier

Hi Gary:

Given the number of posts in the last few days, it hard to jump back in
topic wise. We do try to be civil and maintain some level of composure.
Although, if you were to search the archives, you would find a few moments
where each of us were anything but civil and composed.

> hob�by (h�b��) noun

In other words, the B&W single band and trap dipoles do not come assembled. You assemble and tune it just as though you went out and bought the parts.

Peter,

Are you free to type? Are your kidnappers out of the room? How often do they have a gun to your head forcing you to read and reply to Charles Johnston's messages? It must be awful. It makes me cherish my freedom even more knowing I can killfile or just plain ignore a poster. I feel sorry for you comrade. I have watched you for a long time forced to read and comment on so many of Charles Johnston's messages. It must be hell for you. Be strong!

Glenn

Larry-

the B&W antennas, like most all the commercial wire antennas, do arrive assembled, at least to the point of just attaching feedline, tie-off rope, etc. I think what Doc was attempting to point out is that any dipole may be adjusted by simple length changes. Due to the surondings of most all antenna installations its normal to have to fine tune for best results.

Bests,

Patrick

I have another one: a capacitor is charged with a certain charge/voltage, then
it is dissolved in a non-conductive acid solution (hey, we're talking theory).
Where did the energy go now?

Reg wrote;
"Q meters are part of the environment."

My Heathkit HD-1250 dip meter will indicate the self-resonance of the 1.6 to 3.4 MHz coil by using the 3.2 to 6.6 MHz coil in the dip meter. The dip occurs at the 6.6 MHz end of the dial.

The inductance of the self-resonant coil is given by Heath as 171 microhenrys.

To resonate at 6.6 MHz requires 3.4 picofarads by my ARRL Lightning Coil Calculator. That is the apparent distributed capacitance of my 171 microhenry coil. Looks reasonable to me.

Heath recommends using the plug-in coils this way to determine unknown capacitor values. One can start with the coil`s parasitic capacitance value. It seems to work.

Best regards, Richard Harrison, KB5WZI

You put the metal plates of the capacitor into a non-conducting solution and the charges stay on the atoms of the plates in that solution.

A useful formula is: Q=CE

If the distance between the atoms grows, the capacitance drops and the voltage rises. The converse could occur. If there is no movement it all stays the same.

Insulators can hold a charge without a metal structure. Remember the hard-rubber comb or the amber rod?

Best regards, Richard Harrison, KB5WZI

There was in the 19th century a machine invented to transfer charge from one capacitor to another, the Kelvin Water Dropper; this was later improved upon by Wimshurst. And finally the modern equivalent the Van de Graaff generator. Here transfering the charge augments it and it builds up.
WHY?

Consider what happens when a switch starts to open.
Initially the spacing is very small and a voltage exists across it. As the contacts open the capacitance decreases, but the charge remains constant, therefore the voltage across the opening contacts rises.
No wonder switches arc as the voltage rises above the breakdown voltage of air.

Was this not one of the very earliest experiments using a capacitor (Leyden Jar)constructed from two silver tumblers separated by a glass tumbler.
The assembled capacitor was charged and the charge demonstrated by an electroscope, pith balls.
The capacitor was carefully dismantled and the silver tumblers demonstrated no charge.
The whole was reassembled and the charge was once again demonstrated to be present.
Thus it was inferred that the charge was held in the dielectric glass tumbler.
Using different materials it was possible to determine the Specific Inductive Capacity, (now known as the Dielectric Constant).

Faraday conducted this experiment using capacitors of spherical construction
C1V1 = C1V2 +C2V2
or
C2/C1 = (V1-V2) / V2

The charges were determined by weighing with a torsion balance.

Various dielectric were substituted in one of the condensers the other reference condenser having a dielectric of air.
The ratio C2/C1 is K the Specific Inductive Capacity

Glass
Double extra dense flint 9.90
Dense Flint 7.38
Plate 8.45
Ebonite 3.15 - 3.48
Gutta Percha 3.3 - 4.9 (untreated Rubber)

Mica 6.33 - 8
Paraffin 2.29 (Kerosene)
Shellac 2.95 - 3.73
Sulphur 2.24
Petroleum 2.02 - 2.10
Turpentine 2.15 - 2.28
Distilled water 76.0
Hydrogen at NTP 0.9997
Carbon Dioxide 1.0008

All of these things were common place in 19th century society.
A precision of two decimal places is remarkable considering the crudeness of
the apparatus and stands as testimony to the great care and discipline that
those 19th century experimenters maintained in the ardent search for truth.

Are we as careful, or does our splendid instrumentation make us sloppy not
only about measurement, but also about observation?

Hi Zoran,

Non-conductive acid, hmmm? However, it is still a solute and the
combination of this and the battery makes a solution. The charges are
as free as if they were in solid copper and will recombine.

I would suggest that you wear a face mask, because the energy may go
into a minor explosion.

Hi Gary,

Because a Van de Graff generator accumulates the charge in a truncated
sphere. The charge is applied from within the sphere and naturally
escapes to the outside surface. The geometry of the sphere dominates
the mutual repulsion of like charges that the new charges encounter in
their escape.

Hello !

With some friends I build presently an ATV repeater. The transmitter is designed for the 23 cm band and the output power is about 15 W.
To cover the right area I need an horizontally polarized antenna with an omnidirectional diagram. A gain of about 8 to 10 dB will be highly welcome.
Any idea or tried design ? stacked halo or big wheel or something equivalent ?

Thank you for your help

Hi Cecil:

The devil indeed. He must have poked me a bit to respond.

Considering the situation of multiple EM waves traveling in a guided medium (a transmission line): when multiple waves, all traveling in the same direction in the transmission line, combine to a total wave of zero voltage and current, there will be no net wave propagation in that direction, beyond the point at which the waves combine. A common example of this phenomena is seen in impedance matching with transformers, tuners, etc.

This is not the same situation as waves traveling in opposite directions which can combine at a single (multiple) point(s) to zero voltage or zero current. In this case, each wave will travel past the combination point.

I have been told that modern wave theory requires the continued
independent existence of canceled waves even if there is no net
wave propagation.

I have an old ZEOS Notebook 386 that developed dead batteries when I did not keep them on trickle charge. I carefully cut one of the 2 open and found that the batteries were standard 1700 mah cells that can be be obtained from various nicad sources and soldered together. I can sometimes restore the batteries if not hard shorted by zapping them, but zapped batteries never perform well after zapping, and must be kept on constant trickle charge as you can see from my webpage at http://www.ultimatecharger.com

>
>Best regards, Richard Harrison, KB5WZI
>

The trick is, though, that in the steady state condition, half the voltage on each capacitor corresponds to one quarter of the original energy on each capacitor. When the energy on the two capacitors are summed, the result is that the system only contains half the energy that the original capacitor did. Where did the other half of the energy go? Well, let's think about this.

If the energy on the first capacitor is V volts, then the energy on that capacitor may be found, assuming that the capacity is known, by the equation:

E=(1/2)*C*V**2

If the voltage is halved, then the energy is reduced to one quarter.

Ah, but, you say, if we connect the capacitors up in series, the original voltage is again present. Yes, it is, but the capacity is now one half the original since the capacity of capacitors in series is reduced, according to the equation:

```
1
C=------------------
1 1
---- + ---- + ...
C1 C2
```

Thus, even though the original voltage is present, the energy is still one half because the capacitance is one half the value of the original capacitor.

Ok, so where did the energy go, you might ask.

In an ideal system without resistance, when the switch is closed, capacitor C1 has a voltage on it, and C2 has zero voltage. Thus, current starts to flow from capacitor C1 to capacitor C2. The interconnecting wires have inductance, and this forms a resonant circuit. The current will build up until the voltages on the capacitors are equal. At this point, current continues to flow due to the energy stored in the inductance. The current continues to flow until all of the charge has been transferred to the second capacitor, at which point the first capacitor has zero voltage across it, and the second capacitor has the original voltage on it. At this point, the current starts to flow from the second capacitor back to the first capacitor. This oscillatory behavior continues infinitely, due to the lossless characteristic of the circuit.

Now, if we consider a real world case, resistance in the interconnecting wires, and losses in the capacitor dielectric will cause the oscillation to be damped. After the oscillations have died out, the voltages on the two capacitors will be equal, and will be equal to one half the original voltage, and no current will be flowing.

Of course, one half the voltage on each capacitor corrresponds to one quarter of the original energy on each capacitor, resulting in the complete system only containing one half the original energy that was stored on the original capacitor. Where did the rest of the energy go? It was dissipated as heat in the resistance and dielectric. Thus, energy is conserved, although not necessarily in the original form.

I just saw a quick article at http://lea.hamradio.si/~s51kq on using hardline for a 1250 Mhz dipole and reflector antenna for ATV. A PCB stock reflector is soldered to the outside of the heliax a few inches from the end, and a bow tie dipole is soldered to the inner and outer parts of the coax end.

A similar arrangement is possible for a quick & dirty AO27/UO14 handheld antenna.

Try the B&W site...

http://www.bwantennas.com

There, you'll see under Trapped Dipoles...

All of our trap antennas require measuring and cutting of the wire
segments, and attachment of the traps, center
connector, etc. You will be required to adjust antenna wire lengths
according to VSWR measurements, and solder
or crimp connections. The more bands the antenna covers, the more time
consuming this process may be. It must
be done with care, and strictly in accordance with the instructions.
Otherwise, you will not achieve satisfactory
performance from the antenna.

In other words, it's what you'd do with any antenna, commercial or
homemade.

Message-ID: <D2Cm6.5770$dL4.74018@vixen.cso.uiuc.edu>
Source record: 169515

In an attempt to shed light on my own question, I did some modeling on EZNEC/windows (a wonderfully user-friendly program).....I used a wider-spaced version of 450 ohm feedline by modelling #1 gauge wire spaced 0.583". Zo=276log(spacing/radius) . First I verified that EZNEC behaves well on a simple 1/4 WL of terminated transmission line. I used 20 MHz because EZNEC complains if the spacing is too small in terms of wavelength (I chose the larger #1 wire so the spacing would be wider. I included wires across the ends of the 1/4 WL section, but inserted the source in the center of one, and 450-j0 load in the center of the opposite end. I believe 1/4 WL gives the most severe test, and EZNEC (SrcData) displayed a near-perfect 453-j3, orsomething near that. Now having confidence in that portion, I modeled the off-center fed dipole that I had previously modeled without feedline....it measured 448-j4 ...fed 15.7% from one end of #12 wire dipole. One side of the 450 ohm feedline attached to 3.8' and the other side to 20' . The feed line is 12' long. I used a generous number of segments.... 50 on short part of dipole, 100 on the long part, and 100 each on the feedline, with 9 across the short bottom wire where the "source" is centered. The Current-Tables in EZNEC will now compare currents anywhere in system. As instructions will explain, to compare phases properly, you need to assign your wire coodinates in the appropriate directions, i.e. END#1 of the two sides of the transmission-line wires should start at the same end.
The results were as I expected....as they start up from the source, they are virtually equal amplitude and 180 deg out of phase, but they soon start to depart from that relationship and no longer cancel out their radiation. Of course, the SrcData was far from 450 ohms. Ironically, it "happened to show close to 50 ohms resistive, which pretty much verifies how the End-Fed Zepps operate (or "nearly" end fed.

Probably pretty fair if you bury it under the soil. :^) I have a chain link fence surrounding my property that makes so many parasitic diodes that 80M becomes unusable at times due to generated intermod from several broadcast band transmitters in my vicinity. One "dit" at a couple of watts into the dipole burns out the diodes and everything gets quiet again.

Dave, WA4QAL wrote:
"If the energy on the first capacitor is V volts, then the energy on
that capacitor may be found, assuming that the capacitance is known, by
the equation E=(1/2)*C*V**2
If the voltage is halved, then the energy is reduced to one quarter."

The charge in coulombs (a lot of electron`s charges) on a capacitor is
Q, and
Q=CE, where C is the capacitance in farads and E is the voltage in
volts.

At the original voltage the charge on the first capacitor was Q=CE.
On the two capacitors the charge on each is CE/2, but there are 2
capacitors and the sum of the charges on the pair is the same as that on
the original capacitor.

I believe he's talking of static charges on two capacitors. In that
case, there
would be no current. No current, no power, and the time integral of
nothing
is nothing. Might he be talking about potential energy here?

>
> Energy in a capacitor is the integral of power as a function of time. Power

I was under the impression that, in order to have a phase angle you had
to
have a couple of waves. All you have here is charge which causes a
potential difference between the plates of a pair of capacitors. This
should
store energy in a way analogous to a compressed spring.

>
> Steve, VE9SRB

What you're saying is that given two capacitors, each with equal charge,
the total energy they store in their dielectrics is (Sqrt(E1) +
Sqrt(E2))^2

which, because E1 is equal to E2 comes out to 4 times E1. How did you derive this formula?

: --
: http://web.wt.net/~nm5k

Wow! Good to see ya Mark. You still hanging on 40m?

Yeah, I figured I'd get Dad's call while I could before someone who's got no interest in the family, nor someone who never knew who Dad was, or for what he believed in, got it. Got Extra in '92. Dad became sk in 1988, and his call had to lapse (along with the grace period) before I could apply for it, without a C.O.D. (Certificate of Death). Too much paperwork (and memories) to deal with. I just waited.

While I got you (and anyone else who's reading) I'm looking for replacement dipoles, and/or the little phoenolic/fiberglass rods that are used to support the Decibel Products line of antennas (or similar). Round, short - they keep the dipoles supported, while separated electrically from the standoff for the dipole support.

thanks!

Someone asked how long the sun interferred with earth station reception of the satellite when the satellite comes between the earth station and the sun on several days in the spring and fall.

As I recall, it is a period of several minutes for Houston cable TV earth stations. It depends on location of the earth station.

The earth turns through 360 degrees each 24 hours or 1440 minutes. That means it takes 4 minutes to turn one degree.

The cable company has large dishes with narrow beamwidths, so it doesn`t take much earth rotation to put the sun out of the dish`s boresight.

I have installed several antennas on boats for HF and VHF. Never installed an antenna with radials which might be hazardous on a boat which pitches and rolls.

The Cushcraft may be completely benign. All the antennas I installed were verticals. They work far better over water. HF antennas need a ground plate or reasonable facsimile. For VHF, the coaxial antenna, a type of vertical dipole works very well.

Best regards, Richard Harrison, KB5WZI

A number of years ago I had pretty good luck with a couple of helically wound mobile whips (40 and 15 mtrs.) and mirrow mount clamped to a balcony of an apartment rented at Pensacola Beach and also clamping it to a raised trunk and other temporary locations, operating a Ten-Tec Argosy. At the beach apartment, I used two 1/4 wave lengths of bell wire as radials, cutting them until SWR was low. ... Also had the Ten-Tec Argosy, in the low power position, on a 10-speed bicycle one day with the helical whip mounted on a luggage rack and made a couple out of state ssb contacts.

But EZNEC does not give you the separate impedances looking each
direction at the connection point. With an off center fed dipole,
there is more current flowing in one of the feedline wires than
in the other at the feedpoint and it's hard to choke ladder-line.
I would also avoid using the word "measured" when reporting the
results of a modeling program.

hi,

I was surfing on the net and found G3WOS's article about stacking 50MHz yagis. He mentioned on the article BIP/BOP switching for elevating the radiation angle electrically by phasing yagis in or out-of-phase.

www.uksmg.org/stack.htm

I know that many HF DXers are doing this, but is there any benchmarks doing this on upper part of the VHF (e.g. 2 meters)?

On HF tilted elevation angle can be up to 90 degrees, but what happens with long and highgain VHF yagis? Will elevation change greatly compared with normal angle?

I've seen several commercial matching and stacking products for HF providing BIP/BOP, but is extra 1/2 lambda cable with coaxial relays in other arm of the phasing harness still suitable solution?

Source record: 169535

Hello All!

Since September 2000, I have lost 2 radials from the "cone" part of my antenna

to 50 mph+ wind storms, yet have suffered no loss in signal reception. The

radials are next to each other.

LAFD/PD and Palm Springs come in loud and clear, but I'm unsure just how much longer the present system will hold up.

What/where should I be looking for an upgraded and superior antenna.

Many Thanks!

Alain, just south of Palomar Mtn. (where the 200" Hale telescope is...)

The VERY best portable telescoping mast I've found are those aluminum telescoping masts used by professional window washers. These can be purchased from most hardware stores (or office supply stores) and can be found in lengths up to about 60 feet.

I have a 19 foot one that telescopes down to about 4.3 feet, and weighs almost nothing. With a rubber cap (for chair leg) over the large end, it also makes a nice walking stick.

Ah, thats nothing. I've know lots of people that have fallen thousands of feet and survived (hitting the ground after that killed them).

I agree with all of the above. It sounds very much like an old GPS system.

Source record: 169540

I'm looking to install my 2m/440 rig in my new 2001 Jeep Cherokee. On my previous car I had the MFJ ratchet/multi-angle hatchback mount on the trunk lid. Well after 1 year, it's rusted and corroded. I guess you get what you pay for, Mighty Fine Junk.

Anyways I'm now looking for a new mount. I'm think of buying another mount similar to the MFJ to attach the antenna to the side of the rear hatch instead on up top since the lip of the hatch dips in when you open it. The only other spot I can see is to go along the lip of the hood but I don't like they way that looks.

Any thoughts/ideas/suggestions on a good mount?

Thanks

Chris KC2GLX

Hello

I've had an MFJ 1786 HI-Q loop (10 to 30mhz) for a couple of years.
Since this is the only HF antenna I ever had, I'm not sure
how it compares with others.
It's mounted on the roof of a 4 story apartment building (~35' ?)
and the rig is a 100 watt Yaesu Ft-757
I am not very active on HF but I can routinely reach Europe and
South America from Montreal Canada (is this good, bad, or normal?)
It is easy to use with the motor driven capacitor control right by the
radio.
The only gripe I have with it is because its very high Q, you have to
retune often when changing frequencies.

That's why I mentioned the moon too.
But the sun actually fills a larger angle since solar prominences can extend for millions of miles above the surface and no doubt are hot emitters of RF.

It would be a simple matter to time the ending of a sunset.
For as many as I have watched, I have no specific sense of how long they take.
2 minutes seems reasonable.

It is in fact a satellite antenna. They are used for multi-purpose. If you were to be able to get close to it, you may be able to hear the little motor in there whirring as it keeps up with the signal. It will switch back and forth to get the best signal from a sat, due to obstructions etc. Stand near it, and move around, it'll start moving. These are used to show the position of the unit, as well as "radio and phone" traffic.
Sounds like to original poster was around Indy...

Cabelas is selling a backpackable fishpole that is 14ft and closes to just 15 inches. The St. Louis QUICKY will work nicely on this (about 11 ft) or setting up an inverted-L with lite wire. See www.cabelas.com and look up PANFISH ROD. I set up mine similar to the old St. louis vertical design with the 300 ohm tv wire wrapped on to the base handle. For 20m it is almost 50 percent efficient. Alan KB7MBI

In a word, Yes. Does it work? It does on common
mode (current on the outer shield). Is it 'better'?
Who knows. It can work, so just depends on 'how' you
wanna do it, I guess... Is it a balun? Not really in
this case, what's 'balanced'

Put the antennas on a switch. Un-screw the lead from the
switch from one radio and move it to the radio you want to
use. 'Switching' the radios works, but you want a very
good quality switch, and the unused outputs should be
grounded very well.

Center of the roof with a Comet- SBB-2NMO -146MHz 2.15 dBi 1/4wave
and 446MHz 3.8 dBi 5/8wavedb gain on VHF. At 18" you cant
beat the Gin and the antenna is VERY durable about 1/8 inch thick fairly
tough to bend or break http://www.cometantenna.com/mobile.html

I use a nmo roof mount on my explorer took so debating weather the
"hole" would drop the value....hell most car dealers now could care less
when it comes to trading in your car.

You can find other nmo mounts at the site below however mag. mounts are
more trouble than they are worth when it comes to putting it on top of
an SUV. If you do not want a hole get the window lip mount that will
take less time, and you can put up your antenna w/o getting out of or
climbing all over your truck.

I saw this still being quoted and I noticed that the follow up I had posted is not being included in these quotes.

After a few days of back and forth and after having Cushcraft send me back my original Matching network I did get a call from the Tech and he said I was shipped the wrong box. He then sent me a New Matching network and I installed it. It did the trick and the antenna is working fine (Over 3 months later).

1) I think the entire problem was caused by poor quality control, also the circuit board on the new matching network seems to be made out of a different material.
2) I understand that I could have made my own Vertical but I did not want to take the time and I wanted the best performance I could get. So I paid my 400$ to have a product that should have been trouble free.
3) I am in the market for a second Vertical (For our Cabin) I must say that even though the R8 Performs very well I am not going to purchased another one. I am looking at The Gap Verticals and the Butternet Verticals. I still have not figured out if the Betternet uses a Matching Network like the Cushcraft.

The VERY VERY best portable telescopic antenna mast I've found is the DK9SQ 33ft long fiberglass mast. This thing is designed as an antenna mast and nothing beats it for strength, length and weight. Do a search on DK9SQ and find the web site or find someone who has used one who will then convince you.

The sun and moon both have the same sustended angle of 1/2 degree.

However as the earth's orbit around the sun is not circular, nor is the
moons orbit around the earth, their sustended angles do vary. Hence the
reason for sometimes getting a total eclips (sun or moon) and other times an
eclipsed sun shows a full ring around the moon.

Just remember that there is a good deal of diffraction taking place at
sunrise and sunset.
How much this would affect the time from limb to limb? I don't know.

3937. Heat shrink tube

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-28 06:45:26 UTC
From: Roger Halstead <rdhalste@tm.net>
Message-ID: <a81n6.98$ml.12222@newshog.newsread.com>
Source record: 169560

I recently purchased some N connectors and discovered that they came with a 2" long piece of heat shrink tubing.

When the tubing is shrunk into place I noticed what looked like glue, epoxy, or some kind of resin around the end of the tube and the cable.

I just purchased a 4 foot length of 3M tubing to sealing connectors and discovered that it too has this coating on the inside.

This stuff bonds to just about everything so it looks like it may truly make a weather proof seal. I use a short piece at the back of the connector, make the connection and then shrink a piece that is a bit longer than the connectors and the original tubes. Makes one whale of a solid connection that looks as if, it'd survive under water. Probably not recommended, but it still has that appearance.

Any one know what this stuff is?
Also I don't know if the tubing is UV resistant. That being the case, I don't know if wrapping the tubing with electrical tape for UV protection is needed or not.

The stuff I have gotten from Radio shack always gets a couple layers of tape. Also the stuff from Radio shack does not have the resin coating.

To just one decimal place, I suppose that's the case.
But the sun as an emitter of radio interference is a tiny bit larger than
the visible circle we perceive as the sun.

> > 2 minutes seems reasonable.
> Just remember that there is a good deal of diffraction taking place at

So at equinox to an observer on the equator in the middle of an ocean does the sun appear
to be up for measurably longer than 12 hours?

I have heard the seasonal sun interference with satellite dishes for network radio
broadcasts.
I think that at maximum they last a good bit longer than 4 minutes.

The choke is not the matching section. It's just to reduce common mode currents on the shield of the feedline.
I don't know about the Carr balun, but both do the same job. But, I question how well this works using the choke at the feedpoint. It really needs a second one a 1/4 below the feedpoint I think to fully decouple the line. On 1/2 wave verticals I found using a set of radials grounded to the mast a 1/4 wl below the feedpoint works pretty well. "You use a union for the radial connection the the coax shield". You could also use beads. There are many ways to do the same thing. In many cases, a 1/2 wave vertical will do fairly well without any choke or decoupling at all. But the choke etc, is insurance to make sure your feedline doesn't become part of the antenna. This skews the pattern upward off the horizon. MK

The sphere is conductive and the electrons that make up the charge have
mobility, it is not the metal sphere that causes the charge to build up.
A bucket stood under a small leak in the roof does not fill of itself, the
drip drip drip integrates finally into and overflowing Bucket.
The Van de Graaff generator does not have charges of 4,000,000 Volts
imparted to it, but loads of tiny charges.
It is the energy expended in transferring the small charges that accounts
for the final high voltage.
Think of the electrophorus of the 19th century.

It is interesting that both Sun and moon subtend the same Half degree angle when viewed fromn the Earth's surface, despite the fact that one is 96 million miles distant and the other a mere 250,000 miles. Looks like some Newtonian physics acting here.

> >I did not know so I looked in ARRL books for moonbounce because the sun

> Sun and moon move their own diameter in 2 minutes - useful.

Actuall they don't the Moon takes 27 days approximately so it move in it's orbit 360/27 = 13.3 degrees per day to orbit the Earth.

The Earth rotaes 360 degrees in 24 hours or 15 degrees per hour or 1 degree every 4 minutes. Hence the majority of the apperent movement of the Moon or Sun is due to the Rotation of the Earth.
Note what time the moon sets today and then again note when it sets tomorrow, This is a measure of how much the Moon has shifted in it's Orbit. The actual orbital position of the moon is quite difficult to calculate and it is affacted by external influences such as the gravitational effects of Jupiter. In fact the Bessel Function Tables that we use for some Radio Wave application were first calculated in order to predict the position of the Moon.

It would be even more interesting to time not only the optical setting, but
also the radio setting of the Sun.
A comparison of the times and the delay between them might indicate the
order of the apparent Radio Diameter of the Sun.
Of course edge diffraction and atmospheric and ionospheric corrections would
need to be applied.
Perhaps an Eclipse would provide much better data, especially if the eclipse
is near to Zenith.

Very true, what you can do is provide your own false Horizon when the Sun is
Near to Zenith and time the passage of the leading and trailing edges, at 15
degrees per hour the time will give the angle.
A simple Pin hole projection of the sun should be quite adequate and this
method will permit you to have several goes at it so that you may calculate
an average value and a standard deviation for the sample.
The simplest methods are the best and modern electronic stop watches are
more than adequate to the task.
A similar experiment for the Moon the times can be compared directly to
those found for the Sun.
Determining the Radio Diameter at HF may be too difficult for Hams to
achieve a result with sufficient precision, unless of course you know
better, or can devise a better method, perhaps with AE arranged to produce
an interferometer. Or work in conjunction with another Ham or Hams for

simultaneous observations for widely separated geographical locations. It'd make a nice change from collecting bus numbers. :)

As wrist watches with hundredths of a second are common then local horizon measurements, defined in another post by me in this topic, can be made to 1 part in 12,000, which is pretty good going for Ham work. By taking a large number of measurements a reliable Standard Deviation for the measurements will be available and that should be a good indicator to the Effect.
Doing this Measurement in the Radio Spectrum might prove more difficult, but well within the capabilities of a Ham station and the enginuity of the operator.

> So at equinox to an observer on the equator in the middle of an ocean does
the sun appear to be up for measurably longer than 12 hours?

Look at The Nautical Almanac, full details are given for all seasons.
Look at the figures for civil sunrise and sunset even these will be a good indicator of your local conditions.
Why not go to one of the poles in its Summer time and the Sun will never Set :)

> I have heard the seasonal sun interference with satellite dishes for
network radio broadcasts.
> I think that at maximum they last a good bit longer than 4 minutes.
That is only two optical diameters. the Radio diameter of the Sun is more than the Optical and the Sun Noise does not cut off suddenly, but tails off on a gradient.
Add to that the beamwidth of your receiving antenna and you will be up for a time equal to

Apparent angular radio diameter of the sun time 2 plus the beamwidth of your
receiving dish divided 15 seconds per minute.
Say 1 degree + 15 degrees / .25 = 48 Minutes minimum

The time taken for the sun to set greatly depends in the lattitude
of the observer. On the equator the sun takes the shortest possible
time to set. On the arctic circle at some times of the year the sun
does not set at all - it just runs all the way round the horizon.

In all honesty, you will probably never find a service manual for that piece
of equipment. The manufacturer doesn't want the public to have them. I'm
going through the crap with APC. Good luck.

I had a Cushcrap R7000 that blew up and I now have a GAP Titan. It is pretty decent but is long and top heavy so plan on guying it. There is no matching network, no traps, no radials. It peforms at least as well as the R7000 and a lot more reliably. However, I have become a convert to ladder line fed dipoles. My 82 foot long 160 mtrs dipole (shortened with coils) is fed through a tuner on 160-10 meters. It works great. Far less noise than the vertical - a lot cheaper - a lot easier.

Hi!

My R5 came down last week because of high winds, broken at the antenna-foot.
I will never by an antenna again with the centrte of gravity at the top.
I want to by a titanex HP5. There are no traps and it has an element for
each of the five bands.
Maybe this is a good solution for cushcraft victims.
Has anybody experience with this type of antenna ?

3950. Followup on ATAS antenna for apartment use

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-28 14:20:38 UTC
From: gpewitt@execpc.com
Message-ID: <3a9d0a54$0$46010$272ea4a1@news.execpc.com>
Source record: 169372

OK, here is my progress report.
I put the 80 and 40 meter Isotrons together last week and did the initial tuning with an MFJ-259B. Pretty easy to do with a short co-ax jumper I could make adjustments from my chair. I should mention that the antennas are mounted back to back on a 5 foot mast section held by a roof top tripod and standing in my dining room. I adjusted each antenna before connecting the co-ax tee and the cable to my transceiver (FT-847). I was able to adjust my MFJ antenna tuner on 40 without much trouble and made several contacts in Europe. According to the meters in the transceiver and the tuner I was getting full output. I could not seem to tune the 80 meter band though. This weekend I set up the 20/15/10 meter antennas on another mast and tripod. These have twinlead jumpers connecting all three and the co-ax feeds the 15 meter antenna. After tuning them seperatly with the 259 I finished hooking them up and tried to find the "sweet spots" on each band. Not much luck. I finally got smart and hooked the 259 up -through- the tuner. I set the center frequency of each band on the 259 and adjusted the tuner for the lowest swr. I got under 2:1 on each band and wrote the settings down for quick reference. No wonder I couldn't find the setting for 80 meters without the 259! It's -very- narrow. But I get 1.1:1 when properly tuned in. Since I found the settings I have been able to tune by ear on the receiver noise when changing frequencies. So, using the antenna switch on the tuner to select which antenna stack I'm using and tweeking the tuner for best swr I am able to work on 80, 40, 20, 15, and 10 meters. I have a 6 meter halo that will go up soon and a Cushcraft AR-270 for 2 meters and 440. I did have to buy a duplexer for that one. I was able to complete a schedule with my friend Ron WA9QNN in Grantsburg for the first time (on 40 meters) this weekend.
The Isotrons have tuning stubbs or counterpoises built in and require no ground to work. Good thing as I am living in a second floor condo with no outside antennas allowed.
Am I happy with the Isotrons? You bet. I might even get the 160 meter and the 30, 17, and 12. That might cause a problem though as the 30 meter is meant to go on with the 80 meter instead of the 40. The 17 and 12 are very similar to the 20 and 10. If the 80 is so narrow I'll bet the 160 is super narrow. You have to expect that trying to use such small antennas on the low bands but it does work.
Well that's all for now. 73 Gary N9ZSV

Info on the Butternut antennas is at:

http://www.bencher.com/ant_select.html

Very good writeups, including their manuals in PDF format.

I use a HF6V Butternut as backup for my tree-mounted dipoles. This ground-mounted HF6V is now 20 years old, never been guyed. It needed minor maintenance on some plastic insulators last year.

There is no "matching network", but there is a short section of 75 ohm coax used to transform 20 meter feed impedance down to 50 ohms. The various components of the HF6V look pretty rugged, and Butternut even rates it for the full 2KW. I have fed mine with 500 - 600 watts RTTY years ago with no problems.

I've got some of the DK9SQ masts as well and MANY other items I've made use of over tehe decades. The 10 mtr DK9SQ is a reasonably good choice in the $100 class. One word of caution - it can break. The units are noted as being nearly unbreakable, but I've suffered losses repeatedly of the two smallest sections. A cure for one of the causes is rather simple and only requires installing a plug in the third section which prevents the upper two from falling into the base section. This will prevent the possiblity of snapping these two upper sections while retracting the remaining sections. Most simple fishing poles have a plug installed as mentioned. Too bad a hundred dollar pole doesn't include this ten cent item.

If bent sharply with a light 22 gauge wire these top sections can snap also. Use care when stringing a dipole or other wire with this pole being your sole center support.

If you can live with less than the 10 meter (33') height try a South Bend or Black Widow fishing poles which may be purchased from 6 feet to 20 feet in length for $7 - $20. You will also find extention paint/window cleaning poles at most major hardware stores. These can be fiberglas, aluminum, or a combination. Design accordingly.

Bests,

Patrick
W9GTA

3953. One More Backpack antenna Idea

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-28 15:47:03 UTC
From: Patrick Croft <mai@iquest.net>
Message-ID: <3A9D1D77.7649BBC6@iquest.net>
Source record: 169375

I failed to mention that if your goal is to pack away the mast instead
of using as a 'walking stick' yoou may want to consider one of the many
fishing poles the retract to a foot or so in length. Check here for
such: http://www.cabelas.com

Other outlets offer like items. The smaller and stronger the pole the
higher the cost. Cabela's house brands go for around $20 at the 12'
length.

Bests,

Patrick Croft

Pete, KA0TZK wrote:
"I am often hiking in the country where there are few if any trees so I`ll have to carry all the supporting stuff myself."

The military are expert in improvised antennas. Their choice for ease and performance is the end-fed half-wave.

The length in feet is 468 divided by the frequency in MHz. The ground counterpoise or connection is a "crow-foot" of (8) 25-foot radials.

The military anticipate a sloping wire of 30-ft. elevation down to about 4 feet at the radio set. Their antenna tuners are designed for such an antenna. Trees are possible supports for such an antenna. Insulated extensions of the wire are used for contact with the supports. If both ends of the wire can be elevated to 30 feet or more, so much the better. If trees are not available, a pole or poles are recommended.

For multiband operation, the antenna is broken with insulators. These can all be jumpered for operation at the lowest frequency. Jumpers are removed to permit resonance at higher frequencies.

The military also have a support kit for half-rhombic antennas. The kit includes the wire, insulators, a balloon, hydrogen cylinders, a kite, and other apparatus. It`s too much to back pack unless you are a soldier.

The military have a less onerous suggestion:
"An unterminated end-fed horizontal wire one wavelength long and a few feet off the ground will produce a vertically polarized ground wave in line with the wire, which has materially higher intensity than that from a short whip. This assumes that the wire is fed as described for end-fed half-wave antennas (par.663). The horizontal radiation pattern for ground waves is like a figure 8, the two maxima being in the forward and backward directions of the wire, with the field at 30 degrees from these directions only slightly reduced. This antenna can be used over ground of high or average resistivity, but not over sea water or salt marsh."

This is a type of Beverage antenna which The war Department recommends as a transmitting antenna in several places in their Engineering Handbook. They recommend higher elevations than are often used with Beverage antennas, such as 15 or more feet. But they also say the wire can be placed directly on the ground if necessary, but the efficiency suffers. Thery say that the antenna is as good as a 1/4-wave vertical if their high elevation is used and given the best conditions for the Beverage.

Best regards, Richard Harrison, KB5WZI

3956. Re: Another theory question

Newsgroup: rec.radio.amateur.antenna

Source record: 169377

Well, note that I specified that the question was proposed as part of a job interview. It was less a challenge to design (engineer) the circuit than to understand the underlying physical principles involved. To understand where the energy went requires that you can suggest the various forms energy may take as it goes anywhere.

As I interpreted the question the stipulation that the circuitry was lossless suggested, to me, that there was no loss due to heat. Ruling out that obvious answer led to a discussion, with the interviewer, of other candidate forms of energy. I'll add a few additional facts.

My degree is in physics. My education is not in engineering. The interviewer knew that.

The company was a moderately high tech engineering organization.

The circuit describes the underlying principle for one of the companies' products.

The discussion accompanying the challenge was focused on the statics of the circuitry. Transient or dynamic behavior was not an issue.

Now you know as much as the interviewer and I did at the time of the interview. The answer should be nearly obvious. So, where did the energy go?

regards,

Bill Manley

I wouldn't worry about carrying a mast. A wrist rocket and some 50-lb monofilament line is a lot easier to carry, and unless you're in Antarctica (or some other desert), there's usualy something to shoot a line into. WIth the 50-lb line, you can use the same line to pull your antenna up as you shot into the tree.

Just found the original message and saw that you say that you're
sometimes away from trees. Something like that would make me carefully
chose where I set up rather than carry a mast.

Hi Bill:

Given two equal value capacitors in series, both having a voltage V/2, I
would suggest you look at re-calcualting the total energy in the circuit
again. It is not: Eafter = C1 * (V^2) / 4. Eafter is not equal to
E1 + E2.

I faced the same dilema a year ago.

Ended up with: 5 sets of 2 element monobanders, stacked 2 high.
Most people just call it a 2 element 5 band Quad. Having had it for a year,
I would not go back to a (compromise) multiband Yagi.

3962. 160 Meter Inverted "L" Advice Requested:

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-28 18:39:19 UTC
From: yardleyite@aol.com
Message-ID: <20010228133919.08604.00000226@ng-da1.aol.com>
Source record: 169382

I'd like to ask the antenna newsgroup a question about inverted L's. I would like to build one for 160 meters and have a few questions: Here is my situation:

I can go about 90-100 feet vertical, and just about an unlimited length horizontally. My property is surrounded by talls trees which I plan to hang the antenna from. I already have a 260' flat-top up at about 85' which is a good performer and I'm looking for something that will have a lower takeoff angle to work DX with. I run close to legal limit with my amplifiers. At best my flat-top in reality is a "cloudwarmer" with a takeoff angle of 90 degrees or so. I can't get the 125' height required for a full size 1/4 wave ground plane so I want to do the next best thing.
Here is my idea:

I would like to build an inverted - L and current feed it at the ground via a variable cap. The antenna would be about 90' vertical and either 96' horizontally (for a 3/8 wave antenna) or 170' horizontally (for a 1/2 wave). Since I'm feeding it essentially like a "Marconi" - except with variable reactance at the base, would it outperform my flat -top? Does anyone on the list have a simular configuration?
If so, how does it perform? How does it measure up to a flat - top if you have one as a reference antenna?

I could also elevate the feedpoint to the apex of the vertical and run it against a ground but I don't see any advantage to doing it that way. In either situation I have a large body of salt water that runs directly through my property and I already have four ground rods buried directly in there. I have a 1/4 wave vertical for 75M (61.5') with elevated radials that is a descent performer. I plan to tie the 160M "L" radial system into that.

Any advice will be greatly appreciated. Thanks for reading this post and 73.

Lots of hams buy something expensive and it turns out bad. The necessary
ground plane for a vertical is more effort and expense than a $20 dipole
which may outperform it. Why not try the $20 dipole first?
> SNIP <

Ah, Cecil, once again we find ourselves reading the "dipole may be better
than the vertical" trilogy - or is it octallogy by now? Perhaps the fella
is limited in horizontal-hanging space and sees a vertical as the only way
to go - let's get the requirements nailed down before we start pushing that
tired "vertical, yuk, dipole, YES!" axiom, please. AND, most importantly,
how do you justify the "ground plane for a vertical is more expense and
effort than a dipole" statement? Even you commented favorably on my
multi-band "roll your own" ground plane with low swr and a mere 20 radials.
I'll admit it cost more than $25 (I believe I ended up with $65 in total
cost but I believe that could be reduced significantly with some astute
capacitor shopping) but then it met my horizontally-challenged situation and
got me 212 DXCC confirmed in about 18 months - which was one of the
requirements as well.

P.S. I love cracking on folks that dis the vertical by promoting the
dipole - apples and oranges, in many cases, once the requirements and
expectations are sorted out.

I was pushing economy, not performance. If the performance of a $20 dipole
is satisfactory, stick with it. If its performance is not satisfactory,
then spend some more money for something else. "Why not try the $20
dipole first?" didn't seem very pushy to me.

> AND, most importantly,
> how do you justify the "ground plane for a vertical is more expense and

Last time I calculated the parameters, 1/2WL of wire cost less than 20
1/4WLs of wire. :-) Besides the cost of the vertical, one doesn't get
very good performance out of 1/2WL of ground plane wire. But one gets
pretty good performance out of 1/2WL of dipole. :-)

The basic problem is that a capacitor cannot change its voltage instantaneously. This difficulty is handled in this problem by the introduction of the Dirac function at the moment of switch closure. This function has a very small time duration and a very large amplitude, a "spike" in time. The missing energy is contained within that spike. If we take the Fourier transform of this spike we get a very wideband RF spectrum of coherent radiation for a very brief time. This solution assumes zero inductance and zero resistance in the loop, which is how the problem was stated.

This solution is affirmed by solving the differential equation, using the LaPlace transform method.

I am selling a WJ HF 1000 HF receiver.

The receiver is in good condition and complete of suboctave preselector and operating manual.

Since i live in Rome (Italy) interested buyers are requested to pay this item upon delivery directly to a major express mail service (DHL,TNT FedEx or other) together with shipping charges.

Price is about 2500 US $

If interested contact me via email for further details.

Steve: having served on 4 Navy destroyers during my 21 years in the "Bloody Navy" as an Electronics Technician, I found your post informative. However, your statement, "The choice of upper operating frequency (6 or 8 MHz) is based on the configuration of the HF transceivers used to cover the 2.0 - 30.0 MHz frequency band" may not be entirely accurate. The HF transmitters I remember being connected to the HF fan antennas (principally SRC-16 variations) were operable in the 2 - 30 MHZ range. It was the antenna couplers for the transmitters that dictated which fan they were connected to. The three coupler ranges were, to the best of my recollection, always 2 - 6, 4- 12, and 10 to 30 MHZ. Modern day Spruance/Aegis destroyers and force level ships (e.g., CV/CVN/LHA/LHD) employ a HF system similar to the SRC-16 (I can't remember the Spruance model number) but some Aegis and force level utilize a URC-109 (Canadian model) or a Harris version.

An aside note: The HF transmitters or transceivers that I've worked with, from WRT-2s through URC-32s in the early years (1960 through 1970s) through the modern day URT-23 had an antenna (often 30 foot verticals) specifically "designated"; meaning that xmtr's antenna coupler was located at the base of a specific antenna. However, patch panels were employed where one could switch a transmitter's output around; so that, if a coupler or transmitter went wheels up, you could patch around that defective unit although operating the tuner of one with the transmitter of another could be a challenge.

How'd I do? It's been a while since I've been back aboard a ship to mess with the HF systems - sure brings back fond memories, believe me.

Regards, Jim R.

"VE9SRB" <srbest@att.net> wrote in message
news:zzcj6.9813$X61.710915@bgtnsc04-news.ops.worldnet.att.net...
As a general overview, HF fan antennas installed on Naval ships are generally designed to operate untuned from 2.0 - 6.0 MHz or 2.0 - 8.0 MHz (maybe 10 MHz in some cases) with a maximum SWR of 3.0:1 over the band. Many of the installed fans will have a maximum SWR up to 4.0:1. The choice of upper operating frequency (6 or 8 MHz) is based on the configuration of the HF transceivers used to cover the 2.0 - 30.0 MHz frequency band. Older US Navy transceiver configurations had the HF band segmented into three smaller bands: 2 - 6 MHz, 4 - 12 MHz and 10 - 30 MHz. You will note some frequency overlap. Recent installations segment the bands differently as the transceiver systems are designed to be more broadband.

The HF fan antenna is typically constructed using two fan sections each made with three or four phosphor bronze insulated wires. Each end of the fan is insulated from the ship using delrin insulators. The fans are typically suspended from a main-mast yardarm to a deck level. The fan feedpoint will

be located somewhere on the mast near the upper end of the fan. The fan wires will be connected to a single or dual feedpoint. A broadband matching network comprised of high-voltage vacuum capacitors and lowloss inductors
(sometimes wound using CU refrigerator tubing) will be used to provide the impedance match.

The fan antenna itself is really designed to couple energy to and from the metal structure of the ship and its yardarms. At lower HF frequencies the fan essentially induces currents in the ship's superstructure so the entire ship functions as the "antenna". Integration of the fan into the ship's superstructure is important and that's why many of these antennas are (were) designed using 1/48th scale brass ship models (1/50th scale for metric).

No, I am not replying to myself -

Looking at the problem outside my previous perspective, the statements above are incorrect. If two circuit elements have individual energies E1 and E2, the total energy in the circuit will be E1 + E2. Same as power dissipation - if the power dissipation in one element is P1 and the power dissipation in the other is P2, the total power dissipation must be P1 + P2. Not sure what I was thinking there.

I opted to reply/climb in here, Cecil, simply because I continue to see the "dipole better than a vertical" argument or position when that may be or remain a moot point IF his requirements or limitations dictate a vertical vs a dipole (the ol' horizontally-challenged symdrome again).

Also, what performance are we talking about here? Working "good" DX (e.g., FR, VK0, or DS/HS from South Carolina) on 40 meters? I'll take the vertical any time over a dipole. Again, my friend, what are the requirements?

Regards, Jim R. Oh, go Ford trucks and Power Stroke engines!

Don't you need to guy this mast? Isn't it pretty flimsy without guys? Will it support 14ga wire inverted L without guys? what about using 2 guys and the L leg as the 3rd guy? Will it then bow in the middle thus needing additional guys?

Something tells me to forgo the extra weight of a big mast and just take along a light fishing pole for fishing and use wire antennas. Perhaps a small auto coupler for end fed wire over radials and just toss wire up a tree.

This is sorta interesting looking... I just went to cabelas.com and
found a telescoping push pole (not a fishing rod) ITEM: XA-22-0080
which is made from aluminum and telescopes from 6.5 inches to 12 feet!

Now, that might make a nice 40m loaded vertical right there, don'cha
think? (I'm also looking for very compact antenna ideas, both for
backpacking and for taking to the beach, where there clearly are no trees.)

Could one just add some sort of end loading coil, radials, and then feed
this Al mast itself as the radiator?

What is the "St. Louis QUICKY"?

Have you seen this one at cabelas.com?.... ITEM: XA-22-0080
It is an aluminum telescoping push pole,
which telescopes from 6.5 inches to 12 feet!

I was thinking that one could make a loading coil on PVC form
or something, then slip it around the base of this push pole
where the pole itself becomes the radiating element.

I don't know how to design stuff like this though.
What do you think?

How would you determine efficiency? (You mentioned yours was 50% eff on 20m)
I'd like to build something like this for 40m, perhaps tunable on 20m too.

I would not use 50lb mono line to shoot into the trees because you can't break it or pull the knot out when you get hung up (you will get hung up). I like about 12 to 20 lb mono--the high vis yellow works good--then I tie on my support line--high vis orange or green/yellow 150lb test nylon planer board line. I use a small 1 to 2 oz tear drop sinker and a wrist rocket sling shot, depending on how far you need to shoot it. Keep the lines on factory spool and lay on ground. Shot from opposite of where you want to hall your antenna up. This way you don't have to cut any line and have plenty of mono for when you tangle it (you will tangle it and they don't sell it in the bush).

Good job Jim, you are quite correct. The URT-23 transmitter does operate
over the full 2 - 30 MHz band. The equipment dictating the HF frequency
band separations is in fact the HF multicouplers. The AN/SRA-56 operates
2 - 6 MHz; the AN/SRA-57 operates 4 - 12 MHz and the AN/SRA-58 operates 10 -
30 MHz. Alternately, the URT-23 could be directly connected to a dedicated

whip with a remotely located AN/URA-38 tuner/coupler.

I would have to check in detail to identify the configurations on the DDG-47 (Aegis) and the DD-963 (Spruance) class. I think the newer installations are the broadband Harris equipments that interface with a narrowband or a broadband RF distribution system.

I wrote:
"They say that the antenna is as good as a 1/4-wave vertical."

But, that is for a 2-wavelength Beverage, not just one wavelength.

Here ts what the War Department said:
A single wire two or more wavelengths long supported on poles at a height of 12 to 20 feet above ground is a wave antenna. At the far end the wire is connected to ground through a resistor of about 500 ohms, Crowfoot grounds can be used at each end. I`ve made some omissions only for brevity.

This antenna is directional towards the termination resistor "and is used primarily for either transmitting or receiving vertically polarixed ground waves."

"With two wavelengths of wire, an efficiency equalling that of a guarter-wave vertical can be expected in the h-f band over poor or medium soil."

"The terminating resistor of about 500 ohms must be able to dissipate about 1/3 of the power fed into the antenna when transmitting."

Some of the worlds best scientists were authors of the book when it was written in 1940 to 1944, and this information is excerpted from the book.

Nay-sayers always appear saying a Beverage is hoplessly inefficient for transmitting. I haven`t tried it for transmitting but have used one for reception and it was formidable!

Best regards, Richard Harrison, KB5WZI

You need to go read that again. I missed it too the first time I read
it. The web site says "Telescopes from 6-1/2' to 12'". Unless they
made a typo and really mean do mean 6-1/2". But I don't think so.

If you do a search on "TELESCOPING" there is a "Telescopic Panfish
Pole" that does go from 15-1/2" to 14'. But it's not aluminum and
wouldn't work as a radiator, without adding wire. It would probably
be able to hold up a light weight inverted-v.

George:

Power transformer thump... hmmm musta been running a kW. My puny little power transformer just "clicked".

Ahhhh those 866's. Standing tall and proud, those big ceramic plate caps squating there on top of the bottles, with the HT wire hanging down...

The "glow" actually changed color, shape, and intensity as the current surged through those beautiful bottles with each press of the key. More than a glow... sort of like a captured miniature version of the aurora boreolis inside the 866's glass. Wonderful. You could almost see those individual electrons streaming across.

My 866s were standing tall in the open for all to see from the front. Didn't have to watch the flickering on the back wall of the shack. Of course I had a big sign posted nearby that power supply saying, "Hands Off" and "Danger - High Voltage"! And with that cathode keying circuit you hadda keep your fingers on the key's insulated knob, or Wow!

Of course with the neon bulbs, taped to the open wire feeders with masking tape, flashing in synbchronism with the key strokes, it all kept onlookers at bay. Heh, heh.

Fun! Radio Shacks are just "too clean" today.

-Peter K1PO

I ask you... Where's the "romance" and "glow" in solid state?

I have the AS-160. It covers 160/80/40/20 and held up quite well over the years and 2 moves. Center insulator fell apart. I purchased another aftermarket insulator (not B&W) and also new wire. I thought I would put this antenna together "correctly" using the B&W specs and hung it on a 35' tall fiberglass mast. Boy did it bow over. Even with guys. I adjusted the antenna close to where I wanted it using an MFJ259. Then put the antenna away for when I could hoist it up the tower once I rigged the yard arm and pulley. All set up now and the resonant points are all screwed up. This antenna is location particular. I did not know that and the info did not say--but I should have know better. All the resonant points changed, some to a band edge or beyond. I am going to take it down, but not change it, and just use it for field day because I will just hang it from a tree and it should be the same. Start with 20 meters, then ad a trap and recheck, then 40 wire, check 20 and make adjustments on 20 and 40, then add 40 trap, etc. Antenna works good for local stuff. I like my full size 160 fed with 450 line a LOT better. Much cheaper too!!!!

Cushcraft says to guy the antenna if you use it in windy environments.
Hustler and Butternut advise to guy also. I have had a Hustler 5BTV survive
60mph wind with no guys. I guyed a Cushcraft R7 about 10 or 12 feet from
the top it was invisible to 50mph wind. Especially guy if your area is
prone to high winds and ice or snow loading.

Gary:

We colonialists were once British Subjects, but our ancestors decided the King didn't really know what was best for us, and so we embarked upon an effort to increase our own Q.

Unibond...heh, heh... we don't have that trade name here in the colonies, but since you have "splained" it for us, now we "get it".

Kew? Is that where Kew Gardens is located? Is this the Q that Reg disparages?

Best,

-Peter K1PO, a former Subject.

Since cabins tend to get vandalized and a big commercial antenna is a sign
of possible goodies hooked to it inside, you should consider an ladder line
fed dipole antenna. Take your rig and tuner home with you. On the other
hand, look for a good used Cushcraft R7.

>Think of the electrophorus of the 19th century.

Hi Gary,

You missed this one, and it was your own question!

Charge accumulates on the basis of geometry and the Van de Graff
generator employs a sphere for this purpose alone. Charge always
seeks the curvature of least radius and inside the sphere does not
qualify in the least, but rather the outside is the perfect reservoir.

Think about it, the same belt that moves charge up and into the hollow
sphere could as easily drain the charge (carry it back down due to
mutual repulsion) IF it were collected at the same point it was
applied. This does not happen because the charge "applied" always
seeks to flow to the outer radius and is replaced by newly "applied"
charge from the belt. This charge flow is enforced by geometry (there

is absolutely no way to move a static charge into the sphere from its outer surface).

In a sense, the hollow sphere and belt feed system acts as a mechanical diode permitting charge to move in one direction only. You might want to think of your analogy above with buckets being emptied under water (no net change occurs and the buckets always return to the source full). You will note your explanation offers nothing in the way of preventing this backwash.

Geometry is a first principle.

I can't offer any advice to your question Joe, but I am trying to do the
exact same thing. I have a 100 foot tower and and lots of room out one way
(hoizontally) but limited room the other (opposite) way. I currently have
full size 40 and 80 meter inverted 'V's but 160 band takes a bit more room.

So something like an inverted 'L' sounds interesting but I don't want to
use ground radials. Maybe I am too fussy but there must be a way ..

Richard wrote:
"I am looking at purchasing a multiband vertical antenna."

The War Department`s "Electrical Communication Systems Engineering" has a relative gain table for common antennas in near vertical incidence with the ionosphere for propagation:

Horizontal half-wave, 7 feet high = 0 db

Horizontal half-wave, 30 feet high = +21 db

Sloping 1/2-wave, 5 to 30 ft (broadside)= +12db

Sloping 1/4-wave, 5 to 20 ft (broadside)= +1 db

45-ft top, 35-ft downlead (SCR-188-A)= -2 db

15-ft tuned whip with counterpoise = -38 db

Sky-wave transmission between like antennas.
75 miles, 3 MHz, F2-layer, South Florida.

Of course, for very low-angles the radiation from the vertical tuned whip would look a lot better. But for h-f, horizontal polarization does have advantages.

Best regards, Richard Harrison, KB5WZI

I use a ladder line fed 160 mtr dipole and tuner on all bands. It's a bit touchy on 80 mtrs. The problems associated with antennas exhibiting a high impeadence at even multiples of their design frequency intrigues me.

I have had a theory that because of this phenomena, it would make sense to use a non-resonant length for the dipole (and by that I mean, not cut for the frequency). This is the classsic 100 foot long center fed antenna in the handbook. It would be "off" on all frequencies but since it is not resonant at any multiple, the mismatch would not throw you off the charts. That is why you shouldn't use certain lengths of feedline. Wouldn't the same theory apply to antennas?

You might string up an indoor 10 meter dipole.

You might put an hf antenna on your car, and run coax out to the car
from your apartment.

If you can mount an antenna in your window, look at the Barker &
Williamson AP-10 (I ran one from a 3rd story apartment with success).
See http://www.bwantennas.com/

Check with the arrl web site -- they have a book on stealth antennas.

Otherwise, move :-(

Get more space. Or get higher. Or both.

Hello everyone,

Has anyone on this reflector used a "spud gun" to launch antenna supports?
If so, any pointers. Either post here or e-mail to:

the-irwins@home.com or w1ki@arrl.org

Thanks in advance,

Wayne, W1KI

I've got a Diamond D130J discone antenna mounted 10 feet above my second floor roof. I did a test, and found out that that I'm only get reception up to 1.5 mile away using my icom W32A with 5w output. The antenna I used for transmission is a magnetic mount on my car top. The area is you typical residential area with no tall buildings in sight. Now I'm kind of dispointed.What are your experiences, suggestions? Thx.

I do not pretend to know everything about antennas, I am learning.

I have a dipole antenna up only 25 feet, at one time I had a 80 meter, a 40 meter, and a 20 meter diapole. They worked ok but without the abilaty to get them up in the air I beleive I had a high angle of radiation. (ARRL handbook says that if the dipole is not at least 1.2 wave above the ground it causes the higher angle of radiaton).
With the dipoles I was not getting many contacts outside the USA (My QTH is Michigan)

I now have a vertical and I get much more DX than I did before.
I think the reason for the added DX is the Lower Angle of radiation of the verical (Again the ARRL Handbook says the vertical have lower angles of radiation around 14 degrees)

I have all the room I need for antennas, (5 ach) but I have no trees within 400 feet of the house and only one old tower that was here when I purchased the house (Tower does not tilt). I already have 5 antennas on the tower already.

When I got the vertical I took all the dipoles down except for the 80 meter dipole, (That made the Family a lot happier, my Daughter was calling our house the Beverly Hillbillys Antenna Farm).

All I can say is what my experence is, my Vertical seems to out perform my dipole at my location. I hope to play with making some home grown verticals this comming summer.

I have some feet problems and I cannot climb a tower, so Verticals for me seem to be a good choice.

Does anyone know anything about using multiple verticals at one time?
Is there any advantage?

Yes.

But we are definitely missing something.
Does his base station allow him to hear hams at similar power from much farther distances?
If so, the problem is probably his car transmitter/antenna.

There are too many variables in his problem.

Sounds like something's broken... I can do almost as good with two FRS radios....
Have you tried re-testing it with the original antenna?
Do you have an SWR meter?... Because the Icom 'expects' a little 7" (or whatever) rubber-ducky, well.. ;) I'd be willing to bet that it might do as well or better than the 'stock' magmount...

You can compare performance between your fixed station and other stations, and also compare performance between your mobile station and other stations. Then compare them with each other to see what is deficient.

If residential area propagation is deficient, you could try to find a local repeater to extend your range.

Best regards, Richard Harrison, KB5WZI

Make the dipole 1/2WL long at the lowest frequency of operation, feed it
with 450 ohm ladder-line and don't worry about antenna length. Here's why:

Dipole feedpoint impedances range from about 25 ohms to a few thousand ohms.
What is the SWR on 450 ohm ladder-line for a 25 ohm antenna? 450/25=18:1
Given ladder-line losses on HF, 18:1 is a reasonable upper limit for SWR.
What anti-resonant feedpoint impedance will give an 18:1 SWR?
18*450= 8100 ohms. One is not likely to encounter a full wavelength dipole
with a feedpoint impedance higher than 8100 ohms. If we cut our dipole much
shorter than 1/2WL at the lowest frequency of operation, the SWR can go
much above 18:1. So we have a set of parameters for dipole design.

Note that since the 450 ohm SWR is the same for a 25 ohm antenna and an
8100 ohm antenna, the impedance at the current maximum point on the
ladder-line will be the same for both antennas. In fact, from inside
the shack making only impedance measurements and not knowing the antenna
length or the feedline length, one cannot tell these two antennas apart.

So don't worry about the length of the dipole. Make the dipole 1/2WL
on the lowest frequency of operation and enjoy. Note that I have said
nothing about the radiation patterns which may or may not be a consideration.

You have a serious problem somewhere. Either the antennas/feed line
have a problem or the radio has. I am not sure what kind of setup you
are using as one antenna is on the house and one is on the car. Unless
there is a srious location problem you should be able to use 2 radios
with 5 watts output for several miles. Assuming the antenna is up 25
feet at the house you should be able to work another station in a car at
over 5 miles.

Michael- There must be something wrong- I regularly hit a repeater over
20 miles away with my FT530 with its rubber duck, and hit a repeater
about 75 miles away when I am on a roof-top Cushcraft dual band. I can
count on 20-25 miles when I use a car top magmount (Larsen),except when
I am down in the valley.

Like the other guy, I too was confused with your problem....
Let me see if I have it correct....
1.. You mounted a Diamond D130-J Discone on your house roof (10ft above)
2.. You connected a receiver to it, inside the house.
3.. You drove down the road in your car with your W32A (I had one of these H/H's a while ago too) and transmitted back to the house, using a magnetic mount antenna on the car and connected to the W32A..... Right???

And you are saying your maximum receive range for the D130-J is what...1.5 miles??? That if the car went further than 1.5 miles you either lost it or your reception went downhill (so to speak).....??? And you aren't living in an area without any larger structures (tall buildings or hills) that could block out radio transmissions...?

I hope I got it right.... Well I will at least try to base my reply on the above, hopeful, facts.....

I just recently put up a Diamond D130-J Discone, like about 2 weeks ago and I am very happy with its performance. VERY.
I live in a single level house and my discone is barely above the apex of the roof, well to be honest, it is slightly below it - I just ran out and looked. The tip of the stainless whip only just cuts the apex in height, yet I receive everything... and how!!!! I love it.
I wont bore you with my recent problem but I had a receiver that never really performed that well on V/UHF and I tried many homebrew antennas to improve its reception. I mean to say,, it shouldn't be that hard to receive on a scanner/receiver,, right!!!
My final desperate attempt was to buy this discone as they get good reviews and nobody really has a bad thing to say about them. It still didn't work... To cut things short... It was the receiver that was a tad deaf at V/UHF.
I bought another receiver the other day and all is well. Believe me the discone really does the job and well too. It receives repeaters up to 70 miles away in this hilly country that I live in. Anything within 20 miles is literally "in my face" => full strength.

If you aren't getting similar results with yours mounted, probably twice the height, then you have to have a fault somewhere....
Check...
1. That the Discone is assembled correctly - It was like putting a metallic spider together for me...
2. That it is mounted correctly - Make sure it is not touching anything else and is away from any solid objects.
3. That the coax line/connector is correctly soldered and correctly plugged into the discone, with NO shorts (short to earth etc) or breaks in it.
4. That the other end (at the receiver) is same as No.3
5. That the receiver is on the "correct" frequency and correct mode of reception => AM or FM etc.
6. That you have the correct power supply to the receiver.
7. That the receiver does NOT have a fault in it.
8. That if all above is" A1" then are you suffering the same on all frequencies, not just from your W32A in the car..

Yeah... I know it is a "basic" list of checks but the first thing you should check is always "the most obvious". It's amazing how many people bypass this simple checklist only to curse themselves later when they find one of the above to be the fault...

Michael - I too have had some points in my life when an antenna just gives up on me and it's VERY frustrating to find where, how and why.
Twice now in the past 2 years has my 16 ft Dualband Brainer antenna, all of a sudden, just died down to about half receive strength overnight and transmitting would reveal that I couldn't hit repeaters even 20 miles away. That's when I start at the most simple checks. The first being an S.W.R meter which gave some real wild readings. Both times it was corrosion between the centre lead and the outside braiding at the antenna end, even though the connector was up inside the metal tubing attatched to the antenna base. It was water doing it.... After cleaning and resoldering it, I then wrapped an insulation tape around the connector and first few inches of coax and its been over 12 months now and no problems... yet.

It sounds like you definitely have a "fault" somewhere..... I suggest that it is somewhere in the above checklist....

Good luck.....

Thanks. That was what I was missing. I was sure what you did was possible,
but once I pictured the car on the roof I stopped thinking...
Can you talk to others farther away than that on your mobile? Just asking
to be sure your mobile is really getting out and not the problem in the
test.
Did you terminate the coax yourself? Might try testing it shield to center
conductor for a short. Also try shield to shield on the ends to make sure
there is a good connection to the PL connector.

Is the receiver "dead" on all freqs or just 2M? Did it work before
installing this antenna or is the whole set up new?
As you already know, something is very wrong. With 5W on a HT I regularly
hit a repeater 15 miles away with decent reports. A little noise in the
background but still readable. Good luck and let us know what it was when
you find it.

I guess would depend on what you are trying to work. If far off dx, you
will want to consider the horizontal radiation from the extended wire on
the "L". I assume you want to raise the point of maximum current to
reduce ground losses. Nothing wrong with this, but if you run the
"normal" extended L that is 3/8 wave, you will have a good bit of higher
angle radiation. For medium distances this would be ok, but for far off
DX , not so good. But would still likely beat the pants off the dipole
for long haul. One thing you could do is add a second horizontal wire

and make a "T" vertical instead of an L. This will greatly reduce the horozontal componant, and will act much as a normal monopole. I ran a quick test comparing the two antennas using the elnec demo to see the patterns. The feed impedance doesn't change too much due to adding the extra top wire. I made snapshots of each antenna, and also pasted a clip of the current distribution in the lower right hand corners of each. Both antennas use a 90 ft vertical section , and the first "L" uses a 96 ft horizontal wire at 90 ft high the whole length. The 2nd "T" antenna the same except another 96 ft wire on the other side for a "T". I think I would prefer the "T" antenna for hard core dx. MK

You can see the " L" at http://web.wt.net/~nm5k/invl-1.jpg
You can see the " T" at http://web.wt.net/~nm5k/invl-2.jpg

Both pix compressed to a small jpeg about 35k apiece. Fast d/l..

Yes indeed, it will be charge of an opposite polarity and a machine can be constructed where double the PD between the two spheres may be realised. The practical considerations not with standing.

Is not simply that the charge density is less on the outer surface merely because it is at a greater radius and therefore a larger area, and therefore current does not flow into a higher charge density region on the inner surface, like charges of the electrons repelling.

Should the sphere we connected to a point how much will the voltage increase at the point?

Will charge from the surface of the sphere actually move to the point?

I don't expect a lightening answer BTW.

Next coming to this space the Homopolar generator.:)

Buck, download program VARNEY to accurately analyse performance of dipoles + ladderline + balun + coax + tuner. Instantaneously compare input impedance of feedline on different bands. Compare efficiencies. Check SWR. See where in system the losses occur. Vary feedline and antenna lengths for minimum loss. L-match L and C component values calculated. Observe what happens as frequency is swept over the bands.

I suspect the repeaters you're hitting so far away have antennas that
are considerably higher than the 2-story antenna the original poster
is using. And the repeaters might also have much better receivers. The
original poster has not mentioned what he's using for a receiver, or
how efficient his sending/receiving setups really are. He's operating
simplex, with one ground level antenna, and one 2-story antenna, and
only about 5 watts output. I don't know that he's all that off.

********** RIGHT ON!
****
GIVE THIS MAN A CIGAR

Bill Sabin would have certainly gotten the job.

The energy was dissipated in radiation. With no resonant circuits identified, it would likely have been white noise whose total integrated power (Steve!!!) equal to the difference in the energy before and after.

Now for the end of the story. The circuit was one of the underlying design features of a radar gun which was manufactured by the company.

The interviewer was the Vice President of Engineering. This man was one of the several who shaped my career. (I'm now retired). Not to bore you with details other than to mention that he flew a messerschmit during WWII. A great physicist, engineer and manager.

regards,

Bill Manley KB4XE

4027. Re: 160 Meter Inverted "L" Advice Requested:

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-01 14:34:51 UTC
From: w5omr <no_mail@no_mail.org>
Message-ID: <f6tn6.1910$Fz.677047@typhoon.austin.rr.com>
Source record: 169451

: I'd like to ask the antenna newsgroup a question about inverted L's. I would
: like to build one for 160 meters and have a few questions: Here is my
: situation:
:
: I can go about 90-100 feet vertical, and just about an unlimited length
: horizontally. My property is surrounded by talls trees which I plan to hang
the
: antenna from. I already have a 260' flat-top up at about 85' which is a good
: performer and I'm looking for something that will have a lower takeoff angle
to
: work DX with.

A long time ago, Benjamin Van Wye/W5ZED "Van", took a simple 40m inverted V,
and turned it 90°. The now verticaly polarized antenna is one he called the
"signal Jet".
Presumbably, the direction of the antenna's feedpoint, aimed the direction of
the
signal. Others have tried this, and from what I am told, they have fairly
promising
reports.

What I'm thinking of, is a variation on that theme. You'd like to change the
angle
of attack/approach of the signal from the antenna. How about taking your 260'
Flat top,
lowering the legs (which would reduce your feedpoint Z to something closer to
50ohms) and perhaps fanning them back at an angle, to 'direct' the signal?
For that matter, how about a second antenna, some phasing line, and different
degrees of phasing to electrically change the angle of attack/approach of the
signal?

It's been done. Years ago, it was called a 2-element phased array.

With latching relays to hold the phasing line from one direction to the other,
front
to back reports were seen in the order of 30 to 50db, depending on band condx.

:I run close to legal limit with my amplifiers.

I think most folks in here would agree that the best amplifier is a GOOD working
antenna.

Advertising always looks good.

The antenna is one step removed from a dummy load on the lower bands,
but generally works better as frequency is raised. Don't expect to do
well at all on the lowest bands.

QST review a Gap a while ago, I forgot when, and their conclusions
were about like mine. A ground mounted trap vertical with a good
radial system is much better on most bands.

> Respond in email if possible, I rarely get to check the newsgroups.

The key ingrediant to any of the good antenna switche is a low loss ceramic rotary switch. These are usually more expensive than the garden variety rotary switches, but they offer a higher voltage and current capability, and provide better isolation between switch positions.

If you don't want to build, you could just wander around a local ham fest. I always see them for sale at reasonable prices.

You can also go with relays. Relays allow you to separate the control section from the switching section. You can then put the control portion in a convienent place and have the switching section tucked behind your operating desk. It should be easy to find relays that will handle the voltage and current. Good isolation is usually easier to come by with a relay setup. As long as you don't try hot-switching the relays, contact arcing shouldn't be a problem.

In to any of these setups it would probably be a good idea to include an extra position for grounding the antenna. A good idea to prevent static buildup when your radios are not in use.

Take a look at the ARRL Handbood for some good ideas on antenna and rig switching.

>If so, how does it perform? How does it measure up to a flat - top if you have
>one as a reference antenna?

I've used antennas like that, as have many 160 ops. You really do NOT
want a 3/8th wl inverted L or longer unless you absolutely can not put
in a reasonable ground.

Four ground rods will not be enough, and neither will a few elevated
radials, unless you are happy losing several dB of signal. Even the
loss of two dB can be a big difference if you are trying to work DX.

A vertically polarized radiator will, as a general rule, blow away a
horizontal antenna for any distance more than a few hundred miles. I
have a dipole at 300 feet, and even with that extreme height virtually
all of the time a vertical (with 100 radials) is equal or better.
Sometimes the vertical substantially better!

A lower heghts, a dipole is a dog for anything over a few hundred
miles unless you compare it to a poor vertical. You'll find as a
general rules the only people who swear by low dipoles are those with
poor ground systems, like four elevated radials close to the earth.

Assuming you have a reasonable ground system you want maximum current
over the length of the vertical section, NOT at the top. So you should
plan the length of any flat-top accordingly. Making the antenna about
1/4 wl long from the MIDDLE of the vertical section to the open end
works pretty well.

>I could also elevate the feedpoint to the apex of the vertical and run it
>against a ground but I don't see any advantage to doing it that way. In either
>situation I have a large body of salt water that runs directly through my
>property and I already have four ground rods buried directly in there. I have a
>1/4 wave vertical for 75M (61.5') with elevated radials that is a descent
>performer. I plan to tie the 160M "L" radial system into that.

If you are "tying stuff in" to the elevated ground, and don't actually
have the feedlines and stuff ground isolated, you are not getting
maximum efficiency from the elevated ground system. Elevated radials
systems close to earth aren't all that good anyway even when properly

installed, so you might consider a conventional ground system.

If you use a conventional system with only 30 radials that are 1/8 to 1/4 wl long on 160 meters, you'll be withing a dB or two of anything you can do and far better off than having the elevated system. You'll have less RF floating around, and you will have a feed system that can be (and actually is) directly connected to earth for lightning protection. It will also work very well on multiple bands, something the elevated system won't even likely do on one band.

Of course you'll make lots of contacts even with a less than optimised system, you'll just never be at or near the top of the heap.

Cabela's has "bream" poles to 20 feet. I just saw them at the new store in Dundee, MI on sale for $18.00. The collapse down to about 4 feet. They have rubber caps at each end. All sections are hollow except the tip section, which is a bright yellow/green color with one eye on the end. Overall, the pole is fairly stiff. I put a 60 foot spool of 18 gauge stranded wire at the end of the smallest hollow section and had about 6 inches of sag when holding it at the butt end. The solid tip is pretty whippy, however, your can easily helically wind some wire onto this pole, then take the wire through the eye, then over to a tree, or back down to the ground for an inverted L or V type antenna over radials. I am working on using 2 of these for a portable loaded rotatable dipole.

In reviewing the Cabela page for this item I find you made a slight error in your report -

The unit telescopes from 6.5 FEET to 12 FEET, not 6.5 INCHES to 12 feet. Too long for most traveling ham types. No real advantage to this over a paint or window pole that will cost you half as much. The paint/window poles have the avantage of an adaptable end for mating to PVC and such.

There are telescoping units at achieve the range of 6.5" to 12+ feet. They are typically used in robotic applications by NASA and cost a far more than your super delux rig.

Cecil wrote:
"But one gets pretty good performance out of 1/2WL of dipole."

Page 3-9 of the ARRL Antenna Book puts it very succinctly, "A horizontal antenna will often outperform a vertical for low angle DX work, particularly over lossy types of earth at the higher frequencies.

For honesty in advertising they could have added that you need at least 1/2-wave elevation to get that low-angle radiation. Instead, they left it up to the reader to examine all the charts and graphs that they included.

4034. ARRL Ant Book feedline comments (19th Ed.)

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-01 17:33:26 UTC
From: gene@ews.uiuc.edu
Message-ID: <GJvn6.6920$dL4.90477@vixen.cso.uiuc.edu>
Source record: 169458

The 19th Ed. ARRL Antenna Handbook has some interesting comments concerning feedlines: Quote:
......p. 26-25.."ONE FINAL WORD: This is a good point to debunk a persistent myth among amateurs that a mismatched transmission line somehow radiates. This is absolutely not true! The loss is miniscule. Whenever a line radiates it is because of an unbalanced condition somewhere in the system (on the antenna or its environment or on the line itself) or because of common-mode currents radiated by the antenna back on to the line because of asymmetry in the system. The SWR on the line has nothing to do with the unwanted radiation from a transmission line."...unquote.

..to me, this seems to say that you could probably never get inconsequential radiation from the feedline except in center-fed systems.

......another quote: p. 26-19 "All around the world there are many thousands of coax-fed dipoles in use, where no special effort has been made to smooth the transition from unbalanced coax to balanced dipole." ...."Any minor change in SWR due to common-mode current would be shrugged off as inconsequential." unquote.

Note that they said 'dipoles'...and they discuss that this method would present problems for direction-finding or front-to-back beams requiring deeper nulls.

An unrelated Note: There is an "obvious" error in a figure on p. 5-4 describing the Army Loop: the variable-capacitor shown in the horizontal line to ground, should be inserted in the horizontal line directly above it.

>use a counterpoise,any antenna ideas are appreciated .Thanks

You'll need to counterpoise the counterpoise. Any old hunk of wire
will do, but it will work best if the counterpoise for your counterpoise
is a mirror image of the original counterpoise. In other words, use a
center fed dipole as antenna and counterpoise all in one. No other
counterpoise or ground connection is needed.

It isn't necessary for it to be cut to be resonant at any particular
frequency. It doesn't have to be perfectly straight. But do try to
maintain symmetry about the feedpoint. If the antenna winds up
much shorter than a halfwave, it'll probably be advantageous to
add capacity hats to each end (hardware cloth nailed up to attic
structures is convenient). A tuner may be required, though the
old Swan's Pi net has a fairly broad matching range.

If you use a tuner, a balanced design, and ladder line feed, would
be preferred. (Symmetry is the important thing here to maintain
ground independence and to avoid stray RF in the shack.)

In my copy of the 19th edition, the army loop is Fig 15(A) on page 5-11 of the ARRL Antenna Book.

Agreed, there is a mistake. The loop is shorted in the figure. Won`t work!

The book, however, is correct that imbalance is the principal cause of parallel line radiation. Amplitude of the unbalanced current directly relates to the amplitude of radiation from the line, but is not the cause. The cause is the imbalance.

The book is also correct when it says that dipoles fed directly with coax can in many cases work beautifully with no baluns. I`ve erected many that way myself without a trace of troubles.

Dave-

the Pan fish Poles are nice units for backpackers as well as suitcase travelers. The longest is actually 14 feet and costs $24.99 plus all the usual shipping fees. Not a super strong rod, but quite an asset at $25 just the same. They are well suited for verticals, inverted L's, NVIS dipoles, and other applications in portable situations.

The last robotic satellite pole (9" collapsed to 30' extended seen surplus went on eBay for around a hundred bucks...a fraction of the gov'ts cost (typically $2K).

For supporting coils I suggest some foam pipe insulation of varying diameters. This material is easily layered to host a coil upon a rod and weighs near zero. Its good packing material for the coil as well. I tend to use 2" to 3" diameter coils of 14 gauge or larger wire. Smaller coils tend to get distorted in transit.

You may find it more convenient to place loading coils in the six foot range. While theory demands coils high as possible for greatest efficiency, the practical needs would suggest within reach to allow adjustments.

> thanks jack

I don't live in an apartment, but my subdivision does not allow outside
antennas.
I have a 20/40/80 meter multi-leg, parallel dipole in the attic of my garage
up
about 10 feet. Its not the best antenna, but i've worked 44 states and 3
countries
since i put it up about 8 weeks ago. Since the garage is only 20'x20', the
antenna
zig-zags all over up there, but it works, and with a tuner you can get 1:1
swr.
If your living room in your apt is large enough, i imagine you could tape
something
similiar to the ceiling.

Good Luck!

Hi Richard, Gary,

Just a lucky guess based on years of working with optics. Please note I cannot emphasize "luck" enough, because so much of optical measurement is confounded by the eye's experience (which is vastly superior to almost any detector), and what seems simple - simply because we can see it - is by far and away extremely difficult in practice!

Another note. The radiation from an incandescent light bulb conforms very closely to a black body radiator. The single best detector for this source is any built around silicon. That is because these detectors exhibit a sensitivity curve that also matches the shape of a black body radiator (and few other detectors do). However, there are very few practical applications that use the full black body spectrum of any source.

Making your own HT antennas is simple. A few months ago, I was looking for a VERY small "stubby" antenna for my HT, but couldn't find one and ended up making it myself. For my antenna, I just cut a piece of #22 wire to 1/2 wavelength of the frequency I was going to be using most often (in this case it was 3' 3"). I connected one end of the wire to the center conductor of a BNC connector, and wound the rest of the wire tightly around a pencil. Remove the pencil from the center, and you have a little coil of wire. Then I dipped the whole antenna in a substance called "Plasti-dip" that you can buy at hardware stores. It's litterally a "liquid plastic". After the plasti-dip dried on the antenna, it worked wonderfully.
Note : you might want to test the SWR and tune the antenna before you plasti-dip it :).

Hi Gary,

I've already corresponded with John Fakan, a designer of a million amp
homopolar generator for NASA (you maybe familiar with his work ca.
1960's) - Richard Harrison can fill in for this side thread too.

However, you still miss the point of the sphere. The inside radius of
the hollow sphere cannot contain a charge - period. Any attempt to
place a charge within a hollow, truncated sphere will immediately
result in that charge moving to the outside surface - period. There
is no other operational criteria. There are no other states.

That charge goes to the outside of the hollow sphere by the nature of
charge seeking the smallest radius (the inside of the hollow sphere
does not qualify in the least).

A simple proof of this is with the hollow sphere itself. That is, the
sphere must be absolutely smooth. Any burr or artifact on the surface
will become the smallest radius in the system and charge will flow to
it. In such a case, the charge accumulation at this point will
eventually cause a dielectric breakdown far in advance of the larger
sphere's capacity to store a greater charge and thus discharge the
reservoir. This condition is classic and common practice seeks to
reduce artifacts and radical changes in radius.

When you speak of a "point," that is simply a surface with a smaller radius, which of course satisfies the charge flow requirement. This is also why you see demonstrations of high charge being controlled by pointy instruments from reservoirs of large hollow spheres.

Radius: Geometry is the first principle.

I need a translation. A body may appear black because it absorbs all colors of light. A black body also absorbs heat as we know from black clothes and black automobiles, etc. We also know that black radiates about as well as it absorbs. That`s why heat sinks are colored black, isn`t it?

So, is Richard Clark nsaying the silicon photovoltaic cell is an ideal optical energy detector because it is a broadband nondiscriminatory device which responds equally well to heat and light?

I thought that when an incandescent lamp converted 15 watts into light it was converting 85 watts into heat.

If a silicon cell responded indifferently to heat and light, how could it be used to determine the efficiency of an incandescent lamp?

I guess all one needs are appropriate filters to pass the visible spectrum while rejecting the invisible spectrum, or vice versa.

Best regards, Richard Harrison, KB5WZI

As I strolled after posting, it dawned on me that one could tap a closed loop at points to provide a chosen impedance and use variable capacitors for fine adjustments. But, I dismissed the thought and I still haven`t looked back at the book. If I were making an illustration (figure), I would take care to indicate that I was making a match similar to a delta or a gamma.

Who's transceiver are you using? I work at a company that makes 802.11 radios (also 2.4GHz, but not HomeRF). You might be able to use on of our Yagi's but from your comments I assume there is no connector on the unit.

The idea about the corner reflects is probably your best bet if there are connectors.

Trying to couple another antenna to it will only one cause mistuning on the unit (since by definition the unit's antenna will strongly 'see' your new antenna) and the coupling loss probably won't exceed your new antenna's gain so you will have a washout in net gain. Good luck.

Source record: 169338

Any antenna can be used for a point-to-point, just need two points!!! However when setting up a point-to-point system the idea is to send almost all (ideally all) of your energy towards the other end. Sending the energy in any other direction is a waste since you're trying to get it to a particular location. You use a directional antenna for this reason. Be doing so you can have the points separated by further distances then you could if you used omni's (again directional antennas focus the all the energy where you want it giving a stronger signal). Hope this helps....

I`ve looked at the book again. Fig 15(A) shows a loop with a gap. Each end of the gap is fed by a variable capacitor. Problem is both capacitors are connected to the same point, the center conductor of a coax feeder. Further the feeder center conductor is grounded, But the shield of the feeder is groundeed through a variable capacitor.

It still won`t work. There has to be an impedance between the variable capacitors where they connect to the feeder, but none is indicated. Irv, the text doesn`t say there is enough impedance provided between attachment points of the capacitors to make a tuned circuit.

The text says the loop makes a parallel tuned circuit fed by a tapped impedance matching network. Normally, you need to connect one end of the loop to ground and remove the short circuit on the center conductor to ground to accomplish the described circuit.

I did not see the original QST article, so I have no idea how it was presented. But something was sure lost in translation.

At the suggestion of those who replied to my earlier msg(2m transmission range), I got on the roof and lowered the antenna for inspection. I checked all the connections for shorts and faults, everything was connected properly. As I was measuring across the frequency range using the SWR meter, I noticed a very strange thing. Around 50M, with antenna lowered and placed almost level, SWR reading is below 3, as soon as the antenna is erected the SWR jumps to above 8. Also if I rearranged the cable a little bit, the SWR would vary 2-3 times around 50M. The above does NOT happen in 2m band. No matter how I placed the antenna or the cable, I would get consistent SWR reading around 1.6 throughout the 2m band. So it does not look like a cable problem, does it? Also, with antenna erected,it is about 2-3 feet away from a chimney. Is the metal cover of the chimney affecting the antenna somehow? I'm perplexed. What do you guys think might be wrong? Thx.

Hi Richard,

A Black Body radiator is a source of very wide band emission with a
Gibraltor shaped curve (the steep decline is in the short wave
lengths).

Most of the curve for the standard light bulb falls into the
wavelengths below 600 nM.

The HEAT you speak of is either what you percieve as convection or
conduction. However, there is a vast spectrum (unseen) of radiation
that occurs and is as much light/HEAT as that which you "see/feel."
Silicon detectors are quite well frequency paired with this spectrum -
being most sensitive to the frequencies where the poor lightbulb

peaks, and least sensitive to those frequencies that the poor lightbulb also cannot provide for very well. This spectrum is roughly 1000 nM wide at the half power points. In contrast, the eye can observe a half-power spectrum only 100 nM wide.

Now, as for filtering out IR. This, too, is extremely difficult if you are passing any amount of visible light. Almost every IR filter on the market has huge gaps in its exclusionary spectrum. It is only by luck and happenstance that the applications employing these filters are often blind at these leakage wavelengths.

I still think the prob's in the HT setup, not your 'base station'..
Otherwise, you'd not be hearing anything (besides static) at the house,
unless someone were trasmitting within the same 1.5 mile distance from you
or with quite a bit of power, which I atleast assume isn't a prob......

And have you tried the same test with the antenna that came with/on the HT
yet? I'd bet you'll see very much of an improvement. Lots of people assume
that because a longer wire (ie the taller magmount in this case) often seems
to perform better for receiving, that the same will apply to transmitting..
Not quite so, tho..

Hm, so where's the charge held if the dielectric is air or vacuum? I think KB5WZI got it right.

Anyway, that one was too easy. Here's another one: we wind up a spring which is then believed to be storing a certain amount of kinetic energy. Then we drop the spring in the same acid solution and it dissolves quickly without unwinding. Where did all that kinetic energy go now?

The spring is storing potential energy - not kinetic energy. The same is true
of a book sitting on a bookshelf.

With that as a hint - let's see if someone figures out the answer.

It is not I who disparages Q.

It is others who exalt it, extol it, worship it, even adore and pay homage to it, and place it on a pedestal with SWR and computer programs alongside the Angels.

But everything has a use. Is a widget the unfledged offspring of a widgeon ?

To check if the radio is at fault, try transmitting through the discone and see what kind of range you get - see what repeaters you can access with it. I would suggest that if you are able to access repeaters which are further than 1.5 miles that the problem wouldn't be with the radio or the discone. The next thing to check would be the antenna that you have on the car - they have been known to play up, particularly when you are mobile. When I used to run a 2m HT in the car I used to operate a 5/8 on a mag mount and used to access some of the repeaters at distances of up to 100 km, so don't be to concerned with running an HT in your ca, nor of operating using a discone at home. I am currently running a UHF HT through a discone and I can talk to a mate approximately 30km away - and there are some decent hills in the way between us - and on same discone, I can also on the odd occaision access a 2m repeater at least 100km to the South of me (BIG hills in the way). The SWR situation is a bit on the weird side, my gut feeling is that the antenna is being effected by interaction with the metal on your chimney - more noticeable on the lower frequencies than the higher ones. My experience on VHF and UHF has shown that if possible it is better to get the antenna at least one wavelength (absolutely must be more than a half wavelength) away from the nearest metallic object.

Cheers

Matt

> capacitor values. One can start with the coil`s parasitic
capacitance
> value. It seems to work.
============================
Indeed it does. Although when connections are made to a coil its self-capacitance re-distributes itself and changes somewhat, the value of an unknown capacitor placed across the coil can be determined from the inductance and the new resonant frequency followed by subtracting the value of the stray capacitance. It's accurate enough.

But there's no need to become involved with the stray capacitance at all. All that's needed are the two resonant frequencies and the LF inductance.

In the 21st Century, instead of an 1/2-hour +/- 15% job, the value of a capacitor can be determined by your hand-held analyser within 15 seconds with an accuracy of a few percent. But I cannot say I'm any happier for all these mod-cons.

> KB5WZI got it right.

In air it is in the air, in Vacuum probably in the dielectric materials
neccassary to constrain a practical vacuum on earth.

As a side issue in space the original manned spacecraft had glass windows,
very tough glass windows, but they proved to be a problem because in the
vacuum of Space the charge on them did not leak away and the water that it
was neccassary to vent to space at that time would hang around and stick on
the window by dielectric vacuos adsorption.

They coated the windows with the slightest film of gold, problem solved.

I have one on my wall in front of me as I type.

NASA had a large number of trial windows at the end of the experiments of
which they wished to dispose. They added some a world map of the Deep Space
Network, also in Gold and distributed them amongst the workers, ostensibly
as peanut dishes; a 5 mm thick dished glass elipse 210 x 160 mm

Not a very big window through which to see the Universe. :)

Mine is inscribed

> Anyway, that one was too easy. Here's another one: we wind up a spring
which is
> then believed to be storing a certain amount of kinetic energy.

Actually It is Potential Energy.
Kinetic Energy is what you get when a mass is moving with respect to some
reference frame which contains the observer.

A penduluum has Potential Energy at the two extremes of its swing, the charged Capacitor, this all becomes Kinetic Energy (Minus the friction losses of the air and the suspension) as it passes through the lowest point of it's swing, the Inductive Current.

Pendulum clocks only keep ticking by clever design because Potential Energy from a wound spring or suspended weight via the escapement restores the energy lost to friction.
The most important element to the regularity of a mechanical clock is the stickiness of the oil that is used. Finding the right oil was part of Harrison's success with the Longitude WATCH/Clock. Of course modern clock oils are much better than anything available in the eighteenth century.

>Then we drop the
> spring in the same acid solution and it dissolves quickly without unwinding.

Some trick,
perhaps you should glue the turns of the spring together with some inert glue before you drop it into the acid.
BTW do you also drop the shaft on which it is wound and the case that holds the other end of the spring into this magic acid??

> Where did all that kinetic energy go now?

Loverly mind experiment, but a trifle inaccurate when it comes to reality, I fear

Exactly Bill. But adding a resistor clouds the issue a bit. So lets re
hash the experiment somewhat.
Suppose we use a 2-pole change-over switch instead of a single pole, to
connect the two equal capacitors in parallel. The switch is arranged so
that when the switch is thrown, the connections of one capacitor are
reversed.
Now we charge both parallel capacitors to the same voltage.
When the switch is thrown, the voltage across both capacitors becomes zero.
Where did ALL the energy go?

HAMFEST March 4, 2001 - Lindenhurst, LI

GREAT SOUTH BAY AMATEUR RADIO CLUB and SUFFOLK COUNTY RADIO CLUB
ARRL APPROVED LONG ISLAND HAMFEST - March 4, 2001

LINDENHURST, LI - NY

On March 4, 2001 the Great South Bay Amateur Radio Club will again sponsor an indoor Hamfest-Computer Show. The location will be at the:

Knights of Columbus
400 South Broadway, Lindenhurst, NY.
This is an ARRL approved Hamfest.

There will be radio equipment, electronic components, computers and accessories, software, books, technical manuals, ARRL information, Amateur Radio License Exams, Door Prizes.

Advanced registration is $18.00 each table. Tables at the door are $25.00 each. Contact Walter Wenzel KA2RGI at 631 957-0218 for table reservations. NO TABLES WILL BE RESERVED WITHOUT PRIOR PAYMENT due to the space available.

General admission is $ 6.00. Wife's and children under 12 admitted with no charge.

VE - ARRL - 12:00 NOON at Babylon Town Hall, 200 E Sunrise Hwy, Lindenhurst. For exam candidates please remember to bring your original FCC Amateur Radio license (if licensed), any C.S.C.E. forms that are pending, plus a photocopy of each, pens, calculator, formal form of ID (preferably photo ID), and the examination fee, to the exam session. Current ARRL/VEC fee is $10.00, exact change is appreciated.

Talk-in will be via GSBARC Repeater on 146.685 -600 136.5 PL.

Food Service during the Hamfest will be provided by members of the Knights of Columbus Council.

Information is also available during the GSBARC 2 meter info net every Monday evening at 7:00 PM following the Newsline Report on the W2GSB repeater, 146.685 -600 136.5 PL required. You may also write to:

re: want for Maxcon & Butternut antenna items...

Hello Sailors,

I'm still on the prowl for an Original Maxcon Antenna Interface, if you have one drop me a note as I'd like to buy, borrow (measure it only), rent or talk about the internals. Any of the models sold would be great... I know what it is/was... I just want one to measure it for potential in other applications. yep... I'm an experimenter...

I'd like to locate a used Butternut Vertical that wouldn't be to crazy to have shipped in or pickup near the greater Sacramento (where I domicile). The dual band 80/40 version or the 10 through 80 version would be killer. Let me know if you can sell one in most any usable condition, else I have to go buy one new... ouch..!

Thanks much, Email me at the below address with only ham radio related items, that means no spam please.

Also visit the sonic server listed below for the amateur radio pages...

cheers

Source record: 169360

Because of the limitiation of the mast height I did some experimenting and for 20m+ you can achieve remarkable results with the PANFISH:

MINI-ME: Using NF0R's SLV design you can make a base helix/coil using 300 ohm line (about 23 turns) and a 4m vertical radiator that will achieve about 40-50percent efficiency on 20 and 15m. I use 12 16ft radials made from 7 conductor ribbon line

UMBRELLA: my term for the special inverted-L type antenna. Because of the lack of rigidity at the top in lieu of a single wire I have used three like a guying system and as a top hat greatly improves efficiency without typical coil losses

Unless someone can figure out a way to use viagra with these poles the flxible nature must be delt with whether the PAN FISH, the 20ft BLACK WIDOW, or the DK9SQ.

To work out your own backpackable design you may want to take advantage of this site:
http://www.btinternet.com/~g4fgq.regp/page3.html#S301"

Wow, you were serious. :-)

> For supporting coils I suggest some foam pipe insulation of varying
> diameters. This material is easily layered to host a coil upon a rod

Good idea. Do you wind the coil on some rigid form, like PVC and then use the pipe insulation between the PVC and the rod, or do you wind the coil right onto the pipe insulation? Seems like either would work, but the latter could get smushed.

Sounds like you've maybe used these poles... any suggestions on keeping them upright?

For anti-resonant one wavelength dipoles, 300 ohm line will yield a
higher SWR and may be harder to match than 450 ohm line so you can
expect matching problems on some bands. Hopefully, those won't be
your favorite bands.

Make your dipole 1/2WL on the lowest frequency of operation and feed
it with an integral multiple of 1/2WL feedline. Fine tune the other
bands from there.

for an informed discussion on the GAP you are invited to review the comments at:
http://www.njqrp.org/data/gap.html.

I am a GAP TITAN user and realize like ALL antennas they are compromise. I have been very please with the performance on 40-10m. One of the common problems is folks ask the same question time in and time out. IS THE GAP A GOOD ANTENNA?. Well depending upon your operating needs and limitations the GAP may or may not be a good choice. The LOBE patterns are more than adequate for my location and does exceptionally well for my QRP operations both CW and SSB.

Even the revered DOUBLET has it drawbacks with deep nulls. I do take exception with the folks that make remarks comparing it to a DUMMY LOAD. But that is to be expected in large groups like this. With ALL antennas you need to review first your goals and objectives and then balance with the reality of pracitical limitations you have----MY 2 CENTS (smile) Alan KB7MBI

I used the cheapest 300 ohm twinlead I could buy (Radio Scrap). The antenna was put up as 'temporary' and when I took it down 13 years later the twinlead was as good as
when I put it up. I got consistent compliments on my signals from local and Dx stations.

> DK9SQ.

I could be wrong (not having actually made one yet) but it seems like it
wouldn't be all that bad for the antenna to bend over and flex a little
bit (maybe as much as 5-10 degrees??). Presumably, the first 6-8 feet
will be fairly rigid, and the major flexing will occur only in the top
1/2 or so.

However, the other issue is how to hold the antenna up at all, and there
I can see that guys might help.

The flexing causes the SWR to change, sometimes enough to cause foldback.

> latter could get smushed.

As for coils, I normally B&W, AirDux, or one of the junk box finds.
Winding isn't a difficult issue, just easier and faster to use off the
shelf stock. These are supported via plastic rods as part of the
manufacturing process.

The pipe insulation foam has a seam that allows you to open it. Just
place around the pole, then add another piece around that one,
alternating the open seam. If the coil is 6" long make the foam 6-8".
Two or three layers will be a good fit to allow slipping the coil over
the foam (for a 2"-3" coil). Very flexible and non permanent.

>
> Sounds like you've maybe used these poles... any suggestions on keeping
> them upright?
>

I've used LOTS of variations of poles and LOTS of mounting methods. The
location has a big influence on mounting. Also the type of antenna will
make a difference. If you're attempting simply install a temporary
vertical using a 20' or less composite pole, I suggest a stake mount.
The Sunny Days and Black Widow poles lowest section will fit snugly into
1.5" PVC water pipe. A host of adapters are available at most hardware
stores. I prefer using a 12" length of pipe, placing a TEE on one end.
A carriage bolt or landscaping nail of 8" or more secured to a pipe
cap. Place the cap assembly over the lower end of the TEE. The pole is
simply wedged into the other end of the 12" PVC pipe. This has been
successful in most locations (sand, clay soil, etc.). Should one desire

to install without penatrating earth/surface, a concrete block will make a great base anchor. Improvising is part of the fun, right? These poles weigh about 3 pounds. That makes them easy to work with. The TEE has one other function. The nipple that is horizontal gets a cap as well. On this one I like to install a connector (BNC) and a ground lug. Now you've got a fixed point to run radials from and a secure attachment point for the feed line.

Toss a couple bungee cords/straps into your traveling station package as well. This well let you strap a pole to a railing, gutter, etc.

Using these poles for portable rotatable dipoles or mini yagi's is fun too.

Hope these tips keep you QRV.

If you're going to operate CW or some other low power
favored mode, you might get away with it running no more
than a watt or two.

However, forget working phone on the low bands without at
least several hundred watts output.

Of course, if you do run higher power indoors, you can
expect your VCR, microwave oven, stereo, programmable
clocks, the apartment's thermostat, and anything else that
might use a microprocessor, to perform strange unnatural
acts. Also, the tenants in other apartments (if any) will be
experiencing the same problems and will come looking for the
culprit.

Having lived in an apartment for the first several years of
my amateur radio experience, I can honestly say that you
will have much more success if you were to assemble your low
bands ham station in your automobile and operate as a
mobile.

I've never experienced enough change to cause serious foldback. This includes using the 10 meter long DK9SQ's in 35-45 mph winds at beach settings. They do whip about, but short of a wire breaking or the whole thing falling down, my experience differs. Monitoring the SWR on most any antenna (yagi, vertical, dipole) in a windy situation is likely to so some SWR bouncing.

Dave -

the very top couple sections are quite small on all these types of
poles. The base is typically 1.5" in diameter while the last section is
.0625". They flex considerably as most fishermen will confirm. They
are reasonably strong, but for safety I usually leave the top section
collapsed and attach on the more rigid section for dipoles or L's. In
vertical modes, wrap the wire about the pole a few times helically and
let it sway.

Source record: 169225

1. Forget PVC at 2455 MHz. Even though it is not "microwave oven" lossy, it is low Q and high dielectric constant, throwing all your calculations off. Use polystyrene foam of the lowest density which will provide the necessary mechanical strength. Good luck on weather protection. No other metal or plastic can be in the near vicinity of the helix.

2. Drill and tap two small holes behind the wire which runs from the connector to the helix and is spaced a couple of mm from the reflector. The holes should be about a quarter wave apart. Run two brass screws through the holes and adjust for match.

3. Forget modeling and simulation. They never take into consideration the necessities, like mechanical mounts or matching networks fabricated from actual hardware. Mostly they rely on the scientific version of magic.

A simple modeling program on EZNEC clearly verifies that a pure figure 8
pattern occurs only when you have symmetry with respect to the center of
a dipole: I modeled the half wave in two parts (butted together). I used
two sources, 1% from the middle on either side, then hung a half-wave wire
straight down from the midpoint. Using "free space", the figure-8 pattern
remains perfect, same as if the wire is not there. Then repeated the
same scheme with the dipole divided with wires, 1/3 and 2/3 of the dipole
length....again dropping a single 1/2 wl wire down from the junction.
This completely destroys the deep nulls and destroys much of the direct-
ivity. These effects are also described in the ARRL Antenna book.

Indeed. Excellent suggestions.

I've already got some additional ideas, such as a PVC fitting I've seen that looks like a coupler with four fittings at 90 deg around the sides (for a total of six "ports"). Use the top for the pole, the bottom for the endcap+nail, and the 4 sides for PVC "radials" for stability or when a spike can't be driven in the ground.

From what I gather, VERTLOAD designs something like this, where
mast-coil-rod are all in series, and mast is end-fed with L network...

```
| rod
|
) coil
)
|
| mast
|
coax center---*--L----*
shield |
| C
| |
GND GND
```

Is this correct?

But then how does LOADCOIL differ? I suppose there is some difference in
the feedpoint. (?)

I gather also that in either case, ground radials would be helpful.

> air.

First. You can say the electric field intensity starts out very high at the moment, and at the physical point, where the switch starts to open because of geometry. The field intensity could exceed the break down value of the surrounding air at that point.

Second. No physical circuit is completely inductance free. When the switch begins to open, the resistance change across the contacts is not a perfect step function, the current wants to rapidly fall. Because V=L*di/dt, where L is the always present stray inductance, the voltage rises, trying to maintain the current flow. The faster the switch contact goes from conduction to non conduction, the higher the voltage. For proof just hold the metal probe of an old style Ohmmeter in each hand. Then measure the resistance of the winding of a large motor, or transformer. Keep your fingers on the metal probe tips when you remove one of the probes from the connection point. The shock you get should be convincing enough proof of the above concept. This is also why they stick diodes across relay coils in a DC circuit too.

Reg:

Heh, heh. I know a widget when I see one, but....

I've never known a widgeon... what?

Q is so ephemeral... just when you get it right, it disappears right over
the horizon into infinity!

Reg, have you ever used commercial pot cores and wound precision inductors
from the manufacturer's "iso-Q" contour charts?

I have often wondered if there is a similar iso-Q chart that one can create
for the solenoid inductor.

Iso-Q charts correspond to a given pot core design, which has a fixed
physical dimension and a fixed magnetic air gap resulting in a fixed value
of Al, the charts have inductance on the ordinate and frequency on the
abscissa and consists of closed "loops" tracing the "curves" of constant Q.
It is actually a graphical representation of a surface of Q values over the
co-ordinates of L and f. To be a valid inductor the pot core has to be
"filled" with wire. i.e. once the number of turns is chosen using the Al
value to fix a given L, then the size of the wire must be chosen to fill the
pot core cavity, and then the resulting Q can be read from the iso-Q
contours.

Reg, if one were to fix a given set of solenoid dimensions, i.e. say a
length l and a diameter d could one arrive at a set of iso-Q contours over a
plane of L versus f for a solenoid? Does this make sense? Can your program
plot such a set of curves?

I'm very pleased with my GAP Titan. If I can hear em I can work 'em with 150 - 200 watts. I live in a rural area so I have little problems with noise. My signal reports are great and commensurate with other operators in the area with beams. There is a little benefit that I miss from the directional nature of a beam that might help a little on 40 meters for example.

I'd plan on guying the Gap.

I'd buy another tomorrow. BUT I'm going to strip some wire for local 80 meter work. The polarization becomes an issue locally.

Good luck -- I think it's a great antenna.

Many thanks for your posting.
The PVC material is said to be "good for HF" because
of the microwave oven test, but that is not the whole story,
I was already suspicious, thanks for your input.

What do you think about Teflon as supporting structure?
The TV LNB's use Teflon sheets as cover material.

Commercial makers of helixes use aluminium
as center bar, that works probably because the coil
does a kind of shielding, the interior of the coil is probably
electrically inactive, only magnetically active.
Well, I will do just that, aluminium rod with teflon stays,
leaves enough space in the coil and the wire windings
are not affected by any material losses.

Thanks and best wishes.

> circuit too.

Did you ever hear of a "Metrosil"?
I very high resistance to a low voltage and a low resistance to a high voltage.
Diodes alone do not completely stop the ringing, some form of resistance to dissipate the surplus energy seems to be a good idea.

Actually a resistor in series with a capacitor across a relay coil can do a good job.
But you really need to use the old fashioned solid carbon rods for the function. I have seen sparks jump out through the painted colour code on helical laser trimmed resistors used to damp Relay Back EMF. The air path broke down because the inductance of one turn permitted L di/dt to exceed the breakdown value for paint and air. Since L for a single turn is very small we conclude that di/dt is very large. As I is limited this make di very small indeed, or the frequency is very high.
Presumably this is why they generate noise up into VHF/UHF
By Far the best solution to damping the Back EMF of Relay coils is by fitting a REFER, these devices are a potted R and C in series especially developed for spark suppression. Every Thermostat switch SHOULD have one across it.

Richard:

Thanks for that "widgeon" information. I've never heard that term before, of course I've encountered lots of "widgets", both low Q and high Q widgets. The high Q widgets are the best!

Incidently, I've been to Lafayette, LA a few times. Went to a Doug Kershaw, Jimmy C. Newman concert, and danced with those Cajun girls... and I do have a few Cajun friends from there, but never saw those flying boats to which you refer.

In bayou country, I just saw and rode in the airboats, like the ones they use in the Florida everglades. Been on those swamp airboats in both places, LA and FL. Fun but noisey.

On small flying boats, I've never been on one myself, but I have seen em in action. They are really neat...

Chalk Airlines used to fly a wing of small flying boats out of Miami, FL harbor over to the Bahamas on a regular schedule. Don't know if they still do that. I never flew on them, but used to watch them taking off and landing alongside the ocean going vessels in the harbor back when I lived in Miami.

Would those Chalk flying boats have been widgeons?

ThanQ

Peter Brackett wrote:
"Thanks for the "widgeon" information."

A widgeon is a small fresh-water duck between the mallard and teal in size. Grumman named several civilian aircraft after water-fowl.

Chalk Airlines would probably use larger aircraft unless they were doing charter service. The widgeon only can carry a handful of people.

When I lived in Portugal, I watched a start-up airline unpack and assemble several U.S. surplus PBY flying boats (Catalinas). These are larger than widgeons. They were to be outfitted with a few rows of seats and other passenger amenities. Unfortunately, their fledgling pilots crashed them all before they ever went into regular service. This is no reflection on TAP the government airline. They have one of the best safety records in the business. No reflection on the PBY`s either. They are superb aircraft.

When Peter visited Lafayette, had he poked arund the hangars there, he probably would have seen several widgeons. At least Texaco and Union Oil stationed widgeons there.

Take-off from a runway is unremarkable. They are amphibians. Take-off from the water is something else. At one point the props pick up floods of water and inundate the cockpit. The pilot can`t see a thing. You just hope there isn`t a log or big gator lurking in the take-off path.

Best regards, Richard Harrison, KB5WZI

FEMA bought a bunch of flyaway packs just before Hugo. They are complete PBX systems with cellular interfaces capable of tying their own integral cellsite, or other available cellsites, to long distance satellite channels. (They can interface to surviving wired infrastructure too, of course.) Setup is quick, a few minutes after arriving on site. They fit in a pair of ordinary size suitcases for easy air transport. (These are mostly 16 line T1 grade systems.)

They have priority calling capabilites so that particular phone numbers can be given priority in a disaster. This is a necessary feature to prevent the general public from overloading the systems. Note that *any* cellular system can be programmed to do this, but most haven't installed the necessary software to do it. A few have, and I know of one police department that has gone totally cellular with phone numbers that have been programmed into the cellular system to have priority access in case of emergencies. Non-priority calls can be bumped off the system as necessary to accomodate the priority phones.

By contrast, when the ARC's HF comm van arrived after Hugo, the FEMA folks told them to park it over beyond the dish farm, out of the way. They didn't need HF Morse or voice capabilities. They told them that if they didn't have VHF capability, they might as well go home, because the only real use they had for hams was for local tactical comm with their damage survey teams. They could've used a few extra repeaters to support that, but the ARC van wasn't equipped to provide that, so they came home.

>miles either side of the Mississippi River.

There are *lots* of SCPC systems on rooftops, but not a lot of portables. I doubt many hams would know how to use the ones available to them in the local area for talkback (provided they survived and could be put back in operation). Most of the regular users of the systems wouldn't either.

But someone who did understand them could easily press them into
emergency service. Most hams aren't that someone, because they
haven't self-trained on that sort of technology, and don't have the
information or skills needed to make use of that surprisingly large
and resilient long distance capability. (For one thing, you need to
know how to reconfigure them to contact satellite control, simple
if you know how, and request to be integrated into an emergency
voice or data comm network.)

>In the case of a newsworthy disaster, the media will arrive immediately
>and the dishes will bloom like flowers in the spring. Most of the time
>they won`t be feeding program. They will be obligated to render needed
>communications help via their satellite links. That`s no answer to the
>complete problem, but it sure can help.

My company alone could field 22 uplink trucks and 12 flyaway packs.
All of the flyaway packs could be in place and operating in the New Madrid
area in a few hours. Four of the trucks could be on site in less than 8 hours,
2 are already in the area. The rest could be available in 24 to 48 hours if
given routing priority on the area's damaged road systems. Other broadcast
chains have similar capabilities.

But they aren't setup to handle multichannel voice or data comms. They only
have one two way SCPC capability for scheduling and talkback purposes,
plus one Orbcom messaging unit (in the trucks, the flyaways don't have
this), and the crews may have one or more handheld satellite cellphones
with them.

A digital CO would have to be interfaced with them to provide multichannel.
That's feasible because their modulators and demodulators can deal with
any digital data stream up to 24 Mb/sec (that'd handle 384 simultaneous
calls, or 4 compressed standard definition video channels, our newer trucks
have two independent channels with double that capacity), but it isn't a
capability that's ready to go out of the box. I wonder how many hams could
figure out how to utilize it? Our engineers can, and they know who to contact
to coordinate the satellite resources, because they deal with them every day.

(Someone who knows how to configure systems to interface with the regular
telco systems on the other end is required too. We have that capability in house
as a side effect of our video on demand project, but some other stations probably
don't, and would need to call on local telco people for special terminal equipment
and support. In other words, the bandwidth is there and available, but the knowledge
to interface the systems back into the regular telco fiber network may be lacking.)

So broadcast can bring a lot of bandwidth to bear on the emergency communications
situation, and can do it pretty rapidly, but it isn't a simple turnkey thing by any means.
Knowledgeable and skilled people familiar with the technologies and systems are
required to make it all work.

On another front, Iridium had to be rescued from bankruptcy by DOD (DOD
makes heavy use of Iridium satellite cellphones), but there are 3 other companies
providing satellite phone service, and seem to be doing well with it, at least none
of the latter have declared bankruptcy yet. These latter systems are digital, and

fairly inexpensive multistandard handheld phones are available to make use of them. This is an immediately available resource that can operate independent of local infrastructure.

Also, many over the road trucks now have Orbcom 2 way messaging capabilities, and any passenger vehicle with OnStar also has satellite comm capabilities. These latter two systems seem to be overlooked as an increasingly widely deployed emergency communications resource. They have their own independent power (from the vehicle) and don't need large dishes or special pointing to operate. There is already central coordination and interface to the ordinary communications networks via their Earth stations too. It is likely there soon will be enough of them in any area of the US to provide
the first responder alert that's needed in a disaster.

Then there is Starband, which provides a two way satellite high speed internet link. That's just rolling out in a big way, but it should be popular in rural areas like those around New Madrid where cable modems and DSL phone lines aren't likely to be available in the foreseeable future. The dishes are small, and easily oriented. Anyone with one of these systems, and emergency power, would be able to quickly restore access to the internet after a disaster.

So long distance comm capacity shouldn't be a problem in any major disaster like another New Madrid quake. (In the Northridge quake, the plain old wired internet still worked in most of the area.) There are plenty of satellite systems which can handle it (and any required dish repointing is a trivial task, except for some of the big older C band systems which probably wouldn't fare well in a quake or hurricane). Most hams either aren't aware of them, or wouldn't know how to make use of them for their served agencies, though.

This is a serious shortcoming, because what would be needed most would be people familiar with the available resources, and skilled with interfacing them into coherent controlled emergency communications networks for their served agencies. Most hams aren't self-training to fullfill this role. Most hams are still self-training for19th century style communications.

After the Mexico City earthquake, the amateur NTS was running a *23 day* backlog of message traffic. Amateur HF, as currently used by amateurs, is totally inadequate to meet the comm needs of major large scale disasters, even low priority traffic like H&W messages. For a while it looked like HF packet might be able to pick up the slack, but some poor initial technical choices, and inability to cooperate, has caused that to mostly die away.

If we want to be valuable as comm assets in major disasters, we need to become familiar with the many modern high capacity systems available to us so that we will be prepared to help integrate communications for served agencies. We can no longer be content to provide a 19th century level of service.

Amateurs do have the advantage that some of them are likely to be on the ground at the site of most disasters when they occur. But that means that their homes and stations will also bear the brunt of the damage, and aren't likely to be operable when needed. Most amateurs don't even have emergency

backup power, so when their HT batteries run down, they're out of business.

It doesn't have to be this way, of course, but it mostly is. Most amateurs aren't interested in learning about modern communications systems, or in employing variants of those technologies in their own operations. Most amateurs aren't making preparations to be able to keep their own systems running, or to cooperatively tie them in with others, amateur or non-amateur, if a disaster requiring communications capabilities does occur. (Tying in to available non-amateur systems seems to make some hams unreasonably angry, but it is a vital skill that amateurs interested in emergency comms should have in their bag of tricks.)

Most amateurs are content to consider amateur radio just another hobby, one that lets them yak with friends or compete in contentless radio games to collect postal cards from around the world. That's poor preparation for the day an amateur may need to be able to step forward and be a vital communications asset for his community. In fact, the skill sets that most amateurs do have are counterproductive to the sort of disciplined cooperative enterprise that is modern disaster communications. That leaves amateur radio mostly playing around the edges, and sometimes getting in the way, of the important communications tasks needed to be done in disaster situations.

I'm not saying much that's new here, OpEd pieces have appeared in QST and other places saying much the same things in recent years. We need to rethink our role in disaster communications if we want to remain relevant and useful to our served agencies. We need to develop much better cooperative skills, and we need to understand other available technologies and systems, and ways we can integrate with them to best serve our role.

It should be obvious (but apparently isn't to some) that the romantic image of the lone headphone wearing amateur pounding brass is no longer sufficient to deal with the sorts of communications required by our served agencies. (It never was, but once it was all we had to offer.)

Video has a large role to play in conveying damage assessment. As the
old saw goes, a picture is worth a thousand words. But there is plenty of
satellite equipment that handles only a voice or data channel, SCPC
systems. They are in very wide use by businesses to form private data
networks. The equipment has become inexpensive, and the dishes required
are small. There are also the Orbcom 2 way messaging systems now
installed in many over the road trucks, and the OnStar system installed
in new passenger cars. They are becoming plentiful enough to replace
the amateur as first responder in most cases where a terrestrial cellphone
doesn't suffice.

>
>Why don't the networks use it then - instead of the vans and large
>dishes that they do use?

The networks have very little satellite equipment anymore. They depend
on their affiliates to supply the facilities for feeds. As the largest NBC affiliate,
my company has 22 sat trucks and 12 flyaway packs. We use the trucks for
several reasons. First, they are fully self-contained production and editing
facilities. Second, they have sufficient independent power to supply heavy
lighting loads. And third, they carry big enough dishes and TWTs to let us use
the old (and much cheaper to rent) C band satellites for backhaul feeds. By
contrast, our small light flyaway packs must use the Ku birds. The difference
in transponder rental rates can amount to several hundred dollars an hour
at peak usage times, so there's an economic advantage to using the larger
trucks when feasible.

That's changing as we transition to all digital. With digital feeds, we don't
need as much uplink power or as large a dish to use the satellites. So we
can now use the flyaways on the old C band birds too. Some of the Ku birds
are also getting old, and rental rates on them are declining too. So the
economic incentive to use the big trucks is disappearing. They're still

very useful as mobile production facilities, though, so while the dishes they carry may get smaller, we'll probably keep using some of the big trucks.

4132. Travelling Wave HF antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-03 22:58:38 UTC
From: Michael Hart <mhart@NOSPAM.terrigal.net.au>
Message-ID: <3aa17724@turakina.six.asn.au>
Source record: 169256

Hi antenna gurus,

I would like to find out more about travelling wave HF antennas.
Particularly how they work and how good they are. Haveing one antenna to
cover the entire HF band is very appealing, however they do not seem to be
used much and there is not much information on them.

None of the ARRL or Radio Handbooks I have has enough on them to make any
sense of.

I have found two designs on the web.

One is:

http://www.paws.dircon.co.uk/draka.htm

The second:

was on the ARRL TIS site but seems to have been taken down (from QST
November 1995 pp 22)

I have a few questions about these.

1. Why aren't travelling wave/broadband antennas used more often?
2. Are there any more designs on the web I can view?
3. Is there any descriptions on the web how they work?
4. Is there anyone who knows how to drive NEC who would be prepared to
model the voltage and current distributions of the first design for me
(about every 5MHz)?
5. What is the approximate "efficiency" of a normal wire dipole antenna one
quarter wavelength from the ground?

thanks in advance

These antennas are usually many wavelengths long and are very
directional. I don't have room for one and if I did I don't
know which direction I would aim it.

Michael:

As Cecil points out such travelling wave antennas, e.g. Rhombics, Beverages, etc... are not really applicable to the most common amateur radio uses.

These large travelling wave antennas have found their greatest application and usage in military HF fixed point to point network links or "circuits". In these applications they are permanently set up aimed at a particular very remote other station with which they intend to maintain almost continuous contact. And they are then only used for that particular "circuit".

If you have a particular station with which you wish to maintain a good communications path most of the time and lots of room at each location then you have a clear advantage for this type of antenna, just set up large rhombics at each end pointed at each other.

Think of a center-pivot spray system used in agriculture.

Mount one end to a "center pivot" -- say, one corner of your backyard --
and string the other end to various points for aiming. You only need a
90-degree arc.

Actually, we need 32 MHz of bandwidth for analog satellite video, because we use FM modulation. Of course we benefit from the FM threshold effect, so our CNR doesn't have to be very high to give us a good baseband SNR. (We need a 40 dB baseband SNR to have broadcast quality pictures.)

Our new digital systems are different, we use compression, FEC, and QPSK modulation. We can fit into a quarter transponder bandwidth (8 MHz), and the FEC lets us run with a CNR of only 2 dB. That's a 16 dB total advantage over the analog system. That means much smaller dishes and less uplink power required.

If you're referring to a fullscale, full capability communications operation in relief of a widespread major disaster anywhere, it probably isn't going to happen, anywhere, neither by amateur radio nor any governmental nor other organization(s). Ask the people in Homestead, Florida, many of whom sat for a week before they ever saw or heard from any relief person whatever, following Hurricane Andrew.
Ham radio operators will at best have emergency communications facilities avaliable to use to call attention to their local situations and direct aid coming in, and work with their local authorities as and if needed. Beyond that they will, as usual, handle lots of health and welfare traffic during the aftermath.
There just isn't the necessary impetus put on much more than that. And if hams showed up asking to be allowed to get hands-on time to try to learn any news or other organization's satellite gear they no doubt would be sent packing, and regarded as nuts.

Thanks Peter and Cecil,

Both the designs I looked at cover from the 80m to 10m HF band and both are similar length, if not smaller, than a normal 80m dipole. Further more its also claimed that these types of antennas can also be mounted in an inverted V configuration (see www.bushcomm.com.au). So space wise they seem similar to or better than a resonant antenna.

The rhombics in my Radio Handbook (1979) look more like they are resonant antennas [in contrast to travelling wave antennas] - multiband resonant ones that is with 350 foot or leg lengths just for the 20, 15 & 10 metre bands. I always considered rhombics to be more like V beams with a "director" type element and large rhomics having more directivity by virtue of their multiple wavelength elements. Is this reasonable?

Michael

I used a Diamond antenna for years on our repeaters and when Lightening vaporized it, I couldn't find another Diamond so I put up a similar Comet antenna. I have had repeated problems with the Comet where I have to take it down about every other year and clean the connections between the sections. I have replaced the Comet with another Comet and It did the same thing.

I am thinking about going back to Diamond and I found a Heavy Duty version of the antenna I used before. The Information that I can find dosn't really explain what makes this antenna any better than the regular one.. Has anyone any experience with the "heavy duty" Diamond antenna? What's the difference?

Wally:

I believe they are the same antennas, made in the same manufacturing plant. I
have seen a deterioration in quality in both Company's products over the past two
years. You may be seeing the same thing.

You might want to visit a ham store where you can compare them side by side.

Good luck and 73,

I am in an area with antenna restrictions so I run an attic mounted discone for 2m. For some reason, I am coming over two TV's in my house that are both below me as I am on the second floor. I only thought this happened when I turned my 35 watt amp on but it turns out I do it on stock power as well. Basically what will happen is I will key up and a loud hum can be heard from the TV. Since I am the only ham in the house no one is willing to compromise for me so I have to get this fixed. We have both satellite TV and cable with lines for both running in the attic. Also, the idiot that put in the cable television ran the line through the closet in my room, about 8 feet away from my station and this goes to both the problem TVs. There is no way to move this effectively. I have tried disconnecting the radio from its power supply and running off a battery, high pass filters, a ferrite core around the coax line and power leads to the radio and amp and nothing seems to remedy this problem. I am basically about to give up since I can't use the radio unless no one is home or they aren't watching the problem sets (which are the main ones in the house). Anything I can do? This has been going on for the past few months. Failing a resolution, anyone want to buy an Yaesu FT-411 ht, samlex power supply, and Rf Concepts amplifier?

Thanks

kg4ivt.

4149. Re: shunt feeding a tower?

Other than what's in the handbooks, some notes for you. You'll have to in almost all cases, insulate the guy wires from the tower. But maybe not all of them! Maybe you will wnat to leave portions of them connected up at the top! Read on..

Your beam(s) are, in effect, a large capacity hat, which has the effect of lowering the frequency of the tower. However, thinking about that carefully, you will realize that it is also possible to extend that idea by using the guy wires at the top to make the tower capacity hat BIGGER, thus moving the reasonance frequency of the affair downward if you need to.

Keep that in mind.

I use the gamma match technique style to do this. You'll see it in broadcast installations as a slant wire affair, but I've found a more convenient way to do it at our level of the game.

With the tower isolated from the guys, to start with, then what you do is make a spacer arm set. One will do for the initial tests. The spacing is interesting. I feed both 40 and 80 meter shunt fed towers with a stack of 6 inch TV guy wire stand-offs! What I do is simply pass the shunt wire, no more than just plain old multi-strand copper antenna wire through the little brown plastic insulators. At the top, I run the wire over to the mast and clamp it under a stainless steel automotive hose clamp. Make that triangle big enough so that you don't put undue load on that top TV standoff to keep it from bending when you gently cinch up the final design!

I've never tried this on 160 meters, but it works fine on 80 meters with Rohn 25G. You may find it necessary to use a wider stand-off on 160 than these six inch TV Twin Lead items. As well, if you use the TV items, be prepared to replace the little brown instulators in them every five years or so. They eventually get brittle, crumble, and the wire will begin to touch the metal ring, creating the strangest intermittents you have ever seen. That drove me nuts until I learned to change out the

little brown insulators every now and then!

The initial length for a Rohn 20G self-supporting 60 foot stack with a 1-1/4 inch lightweight EMT conduit stinger on top for reasonance is about half way up the tower, in this case, done this way. That's obviously the 80 meter case. The 40 meter case is about half that, thus there is some element of scale here. It obviously makes a difference how far away from the tower the gamma match section. I've not gotten to the 160 meter game yet, but the logic says that the idea will scale and be about half way up a full quarter wave tower.

That also tells me, just from a thought standpoint, that unless your tower is at least 60 feet up there, shunt feeding it may be a lost cause on 160 meters!

Assumming things are still going OK here, you terminate the ground end of the gamma wire into a variable capacitor. For all my 40 and 80 meter stuff, I use the old capacitors out of BC-375 tuning units and the like. You will need a decent spacing and a transmitting capacitor here for KW levels of power. However there is another trick you can play that will let you use a receiving style unit to set it up. Have some spare RG-8 coax ready if you do that! Ten feet or so is plenty.

You use an MFJ or similar SWR meter with the little power generator in it that will hit 160 meters. Tie it on the free end of that variable and to the base off the tower. Set it to the center frequency you want and take a look at the SWR. You'll adjust the capacitor and the length of that gamma section for minimum SWR. Sorry for the climbing of the stick to move the gamma tap, but that's the way I've always done it.

If you have a willing son, daughter or wife, who will do the work downstairs while you stay up there at the top end to shift the tap, it will save time and effort. In my case, my son was on top until we got the first stalk of the 80 meter 4 square phased array done. Then using the pattern we found, I did the remaining three sticks just like it. My son likes to do the work up there. The man on top is the boss, period, in tower work we do. The phrase, "Thank you!", means you are free to turn loose of what you are handing off to the partner. He finds that fascinating! I know of one ham family marriage that was, perhaps, saved this way, when he and she learned to do tower work together; she favors the top slot! Huge grin!

You will soon learn from the measurement tools whether you will have to add more metal bulk to the capacity hat up there or not. I think you will find that the available literature will suggest that the typical tri-band stack at 60 feet up will yield a functional solution.

When you are done fiddling with that capacitor down at ground level, you may take a chunk of RG-8 or large coax and make a capacitor out of it to take the place of your smaller variable. You use the center for one end of the capacitor, the shield for the other! Do that at the same end and simply cut off the far end until you get the bucking capacitance you

need, leaving enough exposed center insulation at the free end to keep it from arcing. Tape it over with Scotch 33 and forget the whole deal. The correct length turns out to be around two feet on 40 meters, about twice that on 80 meters!

Actually, this is shunt feed, in a way, but compared to the slant wire conventional feed operations in broadcast work, the length of the shunt section is far longer. That's a factor of the spacing etc. In reality, this whole affair is shunt feed, but as well, is approaching what we call a folded monopole antenna.

After looking at what Lawrence Behr did at WTAW for a three element such lower height tower array for WTAW-AM on 1150Khz, I realized that you can likely take a single 66 foot stalk of Rohn 25G, like I have. You can likely then make a separate six inch or so ladder line from top to bottom. You can likely then simply ground it to the tower at the bottom, if you want to use the gamma feed on 80. If you remove the gamma feed on 80 and then unground the longer feed section, and feed it there on 160 meters, my bet is that there is a "Tap Point of Joy", new phrase coined here folks, at which you can alternately feed a conventional quarter-wave vertical on 80 meters or a folded monopole on 160 meters with nothing more than a DC relay throw. You'll be able to get that switching voltage out there down the coax center conductor, if you DC isolate that line, one way or another, at the shack end of the job.

If you do that, don't forget to plan for the lightning mitigation needed. The shunt feed game does *WONDERS* for giving you and easy way to keep the spikes out of the shack, but you still have to plan for the left-overs from the Devil's kitchen!

I've got too much to do at the moment in the computer sustem game to try the dual frequency approach. As sunspot cycle fades, there will be more interest in such things, I bet, and the idea may be worth climbing up there and trying!

Have fun .. I've tried to lay out the practical sum of what is in all the books. That done because, in these deals, they are all cut and try affairs anwyay. In that each collage is diferent anyway, the practical part of how to get it working, at least to me, was the real problem, when I first tried it!

--> Sleep well; OS2's still awake! ;)

Hi to all,

has anyone experiences with the Sommer T-25/S ?

Does it work as advertised ?

You need to determin if the transmitter is comming in on the TV by the antenna or power lines. An RCA receiver at the house was picking up most of my TVI via the power lines. Installed a filter at the TV power line to eliminate that. Try disconnecting the antennas and if you have a VCR playing a tape to see if it is gettig TVI then. On 2 meters you can expect ot get some TVI on the cable channels around 17 to 19 by the antenna as this is the frequencies around the two meter band. Could be poor shielded coax. Are all the connecting cables for the tv the foil shielded kind ?
There is not much you can do at the transmitter to cure the TVI, especially if yo are having problems with under 5 watts.

Is it strictly a 2m discone or one of those discones that covers a wide range of frequencies? You might try an alternative antenna, a homebrew ground plane, dipole or j-pole strictly for 2 meters, and move it around your premises. Might cause less interference.

If it's 12 volts dc to 120 volts ac, just about everybody sells "inverters." Try any auto parts store.

I just got my ATAS installed and everything hooked up through a tri-plexer..
So I fire up the 847 and press the tune button and nothing happens with the
ATAS 100.
I change bands and still nothing...

Any ideas?
PS: I also checked the MENU to make sure "tuner" was set and it is..

Dear Pete,

Being a practical engineer I've never found the iso-Q contour
charts for ferrite pot cores of any use. The operating instructions
for bobbin winding machine have always been the most essential
documents.

I suppose it would be possible to use a solenoid computing program
to assist a team of 4 people to produce iso-Q charts for coils. It
would take about 5 years and a lot of guesswork by which time any
need for them would have completely evaporated.

The present need must be quite small. After all, we've managed very
well without solenoid iso-Q charts for the last 100 years.

Regards, Reg, G4FGQ

"DEFINITELY wrap it w/tape."

My successful experience is that moisture is excluded from coax joints by first wrappinf with electrician`s tape (the sticky, gummy, rubbery stuff) taking care to cover tightly and completely by stretching the tape as you cover. If there is an up and down, start at the bottom and work up as you would with shingles.

After the rubber tape covers the joint, cover with PVC tape, shrink tubing or dope.

it works...but it is a major pain in the a-- to get it to where you want it....it took me all day long to get it assembled and to solder the wires together....(no pl 259 here)..and you have to get a dummy load (another expense) and you have to worry about 2 transformer type of components.....overall ...its a pain.....mine did not work as advertised.....the sommer owner suggested i send back one of the transfromers....but wants to charge my credit card before hell do it....i dont think so....over all the antenna works good on 10- 20 meters....its terrible on 80 and forget 160......i have to use a tuner as well......im using the icom 746......in retrospect i should have got the cushcraft R8 ....i learned the hard way......hope this helps scott

> >
The rhombics and vee beams are both traveling wave type antennas. The
rhombic being a variation of the v beam. "Two V beams back to back".
Both types are non resonant antennas. And both require long lengths in
wavelength to show a lot of gain. The gain is also effected by the
included angle of the wires.Generally , the longer the V beam or
rhombic, the narrower the angle should be. For the V beams , the average
gain can be large if the antenna is long enough. 12 wavelengths will avg
about 14 dbi or so. Two waves long will do about 6-7 dbi. With the
rhombic ant, 12 waves long will do about 17 dbi +-. A rhombic 20 waves
long can do near 19-20 dbi . A rhombic two waves long will do about 8-9
dbi. All these numbers assume the proper included angles used. So the
bottom line is, the antennas are non resonant and usually fed with
ladder line etc, and need to be big to show a whole lot of gain. There
are designs for resonant rhombics also, but they tend to be watered down
versions of the real deal.There are also multiband V beams and rhombic
designs using multiple wires. They used to use rhombics for TV reception
in the old days. For the VHF frequencies, one not too awful big could
have a lot of gain. But most went to steerable antennas. Also for best
results a rhombic should be at least 1 wavelength high. Same as a
dipole. Don't confuse these with beverages which like to be near the
ground. MK

Reg:

Iso-Q curves...

Well... back in the "old days" in one of my former electronic company employers, when we were designing and selling a lot of "precision" LC filters and LC group delay equalizers, we made extensive use of pot cores and pot core iso-Q curves.

Most of those filters and all-pass group delay equalizers that we designed were for use in the frequency range from audio up to a couple of MHz and were never in the HF band.

In many cases they were "narrow band", i.e. say spanned a 3.4kHz voice channel say in the "group" band of 60kHz to 104kHz, or VFCT, voice frequency carrier telegraph channels, etc...

These were "precision" filters and equalizers, often of very high order. The highest order that I ever personally designed and put into production was of order 22. i.e. a precise design comprising 11 inductors and 11 capacitors, not counting Norton transformations and tapped inductors, etc...

Now in order to get the actual production filters to "hit" the design spec within the desired tolerances [Which were often of the order of +-0.1dB in the passbands], we had to actually synthesize "pre-distorted" designs.

We had to pre-distort the inductors for two effects, both the Q and the stray capacitance of the coil, or self-resonant frequency of the coil. In practice most of our capacitors could be considered to be "ideal" and consequently we seldom pre-distorted a design for the C's. We did this only for the L's. This is/was called "semi-uniform" pre-distortion.

To do this predistortion accurately we had to know the inductor "Q"s in the filter passbands fairly precisely, we used the iso-Q contours to help us with this. We also had to pre-distort the design for the "effective or apparent" inductance. i.e. the actual apparent inductance in the filter passband taking into account the stray intra and inter winding capacitance and the self resonant effect of the inductor. In other words we actually had to offset the design inductance by an amount to take into account the capacitive reactance of the inductor stray capacitance, at least across the band of interest. Our precise value of design inductance was the apparent inductance at a given frequency of the structure of the inductance and stray capacitance acting together. Below resonance, this apparent value of L, call it Lapp, is always slightly higher than the actual inductance. The deviation of Lapp from L rising as the self-resonant frequency is approached.

The pot core manufacturer's iso-Q contours and their "effective inductance" correction factors allowed us to design and manufacture inductors which were then used in the "pre-distorted" precision designs with great accuracy. The iso-Q contours were actually plotted on a plane of actual or real frequency f versus apparent inductance Lapp.

We used computer analysis and synthesis to generate the "pre-distorted" filter and/or equalizer designs. i.e. we would begin with a specific ideal "target" design, say for instance a Cauer Parameter [Elliptic Function Filter] filter of order12 or more... then we would first design the ideal filter to get the first pass non-predistorted values for L's and C's... then we would design, on paper, the "ideal" inductors required. Then we would find the actual practical Q for those inductors from the iso-Q contours provided by the pot core manufacturer, within our passband of interest.

Then we would average the value of those inductor Q's to get an average coil Q which we called Qavg for the whole filter. Then we would take the mathematical "ideal poles" of the ideal filter and pre-distort or shift them to the right [towards the jw axis] by an amount equal to 1/2*Qavg. Then we would use our computer algorithms to re-synthesize the whole filter from those "pre-distorted poles". We generally did not pre-distort the stopband zeros, since the "error" in the notches in the stopbands was tolerable, it was the passband errors that really caused the difficulties. And we would then design and manufacture the actual filter using the new, nearby, values of inductors obtained from the synthesis of the pre-distorted design. And... presto... when the filter was built and put in production using the actual coils [rather than the mathematical ideal coils] the actual filter would be "right on the money". Note the capacitor values would also now be slightly different as well.

Thus we could design filters that used practical finite Q coils, including the effect of self-resonance, to manufacture very nearly exactly perfect precison filters and equalizers. Our competitors often tried to achieve the same thing by adding additional correction amplitude and delay equalizers to a poor non-predistorted design. i.e. since they did not know how or could not pre-distort the design, they just took the poor design and added a bunch more of inductors and capacitors to correct the errors in the design. Consequently our precision designs cost usually 20 - 30% less than theirs and were much more precise, with fewer parts and smaller altogether.

Pre-distortion for all-pass group delay equalizers was a little more complicated, since the group delay eqalizers have both poles and zeros that need to be pre-distorted. No one seems to care about this passive LC all-pass equalizer stuff anymore today folks do delay equalization digitally today, but we did some really neat stuff in that passive LC all-pass network area! I believe that we were the only firm that did pre-distorted delay equalizer designs.

Over a period of about 10 years we created perhaps 50 different passive LC filter and group delay equalizers, and produced them in many thousands of units for use in all kinds of commercial FDM equipment.

And so... I don't know about others, but we did find iso-Q contours to be both useful, and profitable.

Now I agree that the average ham or person doing low order, low precision, designs in the HF band would have no use for iso-Q contours, however...

those curves do illustrate some interesting and practical physical phenomena, and help with the intuitive understanding of the underlying physical phenomena, for instance...

The fact that the iso-Q contours for all pot cores seem to be closed curves in the (Lapp, f) plane is interesting.

Why are the curves all closed? What can we learn from that?

And.. the fact that there seems to be only one particular (Lapp, f) co-ordinate where a particular physical dimension of pot core inductor has maximum Q... why is that? i.e.

the Q surface over the (Lapp, f) plane is mono-modal. Why? Why does the maximum occur where it does? etc...

and so... getting back to the thread topic, I have often wondered for a solenoid single layer inductor... of length l and diameter d...

what is the maximum value of Q?

....and for what value of Lapp and f does it occur?

etc...

is there in fact a unique single maximum value of Q for a solenoid on the (Lapp,f) plane?

For instance, can your program be used to plot the maximum values of Q for a solenoid of dimensions l and d over the range of 1 MHz to 30 MHz, and the range of 1uHy to 100uHy... I presume that the wire diameter at each point would be set by the program to maximize the Q at any point etc....

Then once the first set of iso-Qs for a given (l, d) are plotted, one could go on to plot curves for various (l, d) values to perhaps eventually discover the question which we all desparately want answered!

What is the solenoid coil which has the highest Q value in the HF band?

i.e. does there exists a solenoid of given l and d, wound with copper wire and of apparent inductance Lapp, at frequency f which has the maximum value of Q of all possible inductors? If so, what is it? Can we not all use it?

Let us designate this optimum solenoid HF inductor the "closest inductor to the perfect inductor" and we will name it the "Henry" or something like that!

Then, for it's discovery, I will personally offer the "Brackett" prize! A free dinner at KFC!

How about it? Your program "solenoid" is a good start!

Best,

-Peter K1PO

>>>Pentagon's latest weapon: a pain beam

Computer rendering of proposed Vehicle Mounted Active Denial System prototype

March 2, 2001
Web posted at: 3:02 p.m. EST (2002 GMT)

WASHINGTON -- The Pentagon is touting a new "non-lethal" weapon designed to control threatening crowds by using a directed energy beam to inflict a painful but brief burning sensation.

The weapon could be deployed during peacekeeping missions when deadly force is not necessary, military officials announced Thursday.

The weapon, called "active denial technology," was developed by Air Force research laboratories in New Mexico and Texas as part of a multi-service program run by the Marine Corps.

"This revolutionary force-protection technology gives U.S. service members an alternative to using deadly force," said Marine Corps Col. George P. Fenton, director of the program at Quantico, Virginia.

The weapon is designed to stop people by firing millimeter-wave electromagnetic energy in a beam that quickly heats up the surface of the victim's skin. Within seconds the person feels pain that is akin to touching a hot light bulb.

Like being burned
"It's the kind of pain you would feel if you were being burned," said Rich Garcia, a spokesman for the Air Force Research Laboratory at Kirtland Air Force Base, New Mexico. "It's just not intense enough to cause any damage."

The Pentagon has made a strong push to develop "non-lethal" weapons in the aftermath of a humanitarian mission in Somalia in 1992-93 that put soldiers in the line of fire in urban areas where civilians were present.

A demo version of the technology can test the level of pain

The beam reaches only 1/64 of an inch underneath the skin, causing no permanent injury, Pentagon researchers said.

"When it penetrates in, it activates the pain sensors, and you feel a lot of pain," Garcia said. "But there's no damage. It truly is a non-lethal device."

Michael Murphy, an Air Force lab researcher, said the beam could be used safely.

"We've tested 72 humans that have had over 6,500 exposures," he said.

The military will test a prototype of the weapon on goats and humans in Kirtland over the next few months. The Marine Corps said $40 million was spent developing the weapon during the past decade.

The Marine Corps plans to mount the microwave weapon on top of Humvees, the Jeep-like vehicles used by both the Marines and the Army. Later it might be used on aircraft and ships, officials said.

The weapon could be fielded by 2009, officials said.

Concerns remain
William Arkin, senior military adviser to Human Rights Watch, questioned whether a pain weapon would be safe to use against civilians in combat situations.

"What about children in the crowd? What about pregnant women and the elderly?" he said.

"We have developed a non-lethal weapon which causes pain. What happens when someone continues to walk toward the source of the high-power microwave? What happens when panic ensues in a crowd as a result of high-power microwave? What happens when it's focused on someone's eye?" Arkin said.

Another Humans Rights Watch activist expressed other concerns:

"It may fall into the (wrong) hands. It may be eventually sold to other countries to police forces, military forces that don't have the degree of accountability that you see in this country," Joost Hiltermann said.

I ask you... Where's the "romance" and "glow" in solid state?
>
> -Peter K1PO

In my puter screen...:) . I remember when I first got my novice and
bought a viking valiant transmitter. It had a pair of 866's. I didn't
know about the blue glow as no one mentioned it when I bought it. I
fired it up, and the tubes went blue, and I thought, uh no, gassy tubes.
I shut it down and went and bought a pair of new 866's. Put em in, and
it still glowed blue. Uh no.... This rig has a serious problem I
thought. I called the guy up where I bought the tubes and I finally
found out that glow was normal. Boy, I felt like a dummy....Oh well,
another day, another 2.41 cents. I still have a "semi-tube" setup with
the TS-830 and the henry 2K classic, also still have a bunch of drake
gear, but my tube days are quickly numbered. Lately, I use the 706 more
than the 830, and am fixing to go solid state for an amp. Also building
a level converter to puter control the rig. Already run the audio thru

the sound card, so after I get the rig control, I'll be almost all puter driven and audio manipulated, with the rig a CB sized 706. I might get a 746 later for a bigger house rig. I've been trying alot of digi stuff etc. Was listening to MFSK16 on 80m tonight. That stuff copies pretty well thru the noise on 80m. This setup Also does good SSTV etc. I copied a few pix from the amsat net on the local repeater the other day, and looked like digi-snapshots. Real nice quality. The 706 easily lets me do all this stuff on any band up to 440. I used to like the "big" shacks with 40 tons of gear laying around looking impressive, but now I'm about to the point of a puter controled CB on steroids..:/ A lot has changed in the past 10 years. Peter Brackett wrote:
"In many cases they were "narrow band", i.e. say spanned a 3.4kHz voice channel say in the "group" band of 60kHz to 104kHz, or VFCT, voice frequency carrier telegraph channels, etc."

OK, except the usual frequency division multiplex allows 4kHz per voice channel to permit signaling and supervision at the edge of the voice channel. The bandwidth retained for the voice band might vary slightly from 3.4kHz.

The "base group" is normally 12 of these 4-kHz channels between 60 and 108 kHz. These same 12 channels (the base group) are used over and over again throughout the baseband by translation. They are simply heterodyned either directly or via some super-group to any group-spot in the baseband.

The 12-channel group occupying 108 to 156 kHz is exactly the same 12-channel group as that occupying the 60 to 108 kHz spot. It has just been translated.

Modern analog practice is to use a universal channel which can be programmed for any carrier frequency multiple of 4 kHz within the baseband. These are SSB channels. Only a single modem is needed as a replacement for any channel modem in the system.

As Peter implied, it is desirable to have the same delay for every frequency in the baseband.

Filter flanking is a big deal to fit all the channels together.

Peter also wrote:
"Below resonance, this apparent value of L, call it Lapp, is always higher than the actual inductance."

In my experience, Lapp was a manufacturer of high-power vacuum tubes, vacuum capacitors, and ceramic insulating hardware.

Best regards, Richard Harrison, KB5WZI

4170. Ringo vs. J-pole

Hello Richard:

I note that you too messed around with FDM systems. I used to do a lot of passive LC filter and equalizer designs but those skills and knowledge are now un-marketable.

In recent years I have set my objectives toward a similar task, but using more modern technology (DSP), and am now committed to putting more bps/Hz/Dollar down long runs of twisted pairs of copper.

Next we are looking at doing the same for single strands of Silica. Sort of like Kestrel Solutions and Centerpoint are doing.

Electrical waves, light waves....

Some things never change!

Best,

-Peter K1PO

Dick Elliot wrote:
"The news reporters asked a lot of questions and the only answer that was given by the government was that it was harmless. What a bunch of BS!!!"

Yes, it may be quite bebeficial in the long-run. I worked for years in the middle of an HF megawatt field. An accidental contact with a 50-KW transmission line turned one of my ears to a black lump that resembled a piece of coal. No permanent damage. My experience may have been therapeutic. We had over 200 people working in and around that transmitting plant and saw no unusual health problems. In fact, it was an unusually healthy group. Our experience may have been therapeutic, The mileage of others may vary.

A friend brough over a burnt-out tuner for me to fix. The inductor
was removed and all of the balum and out-put wiring. Does any one have
a copy of the skematic that they could e-mail me to at least make an
L/C combination T-tuner using the present variable cap and a junk box
roller inductor. I just want to use the originial design as a guide.

Message-ID: <3aa3b4b2$0$1519$6daed22a@news.infinet.com>
Source record: 169203

Shortly, the XYL and I will be moving to a new QTH with lots of land (4 acres), but no trees. I'd like to quickly (and inexpensively - lot's of other expenses right now) put up a wire antenna (such as a Carolina Windom) so that I won't be off the air after the move. The towers have to wait for more cash.

What's the least expensive way to get the antenna 40 + feet up? I've looked in a couple of books and they have plans for a simple mast made from 3 20 foot 2x4's. For the Carolina Windom, I suspect I'll need at 3 supports. There's a caution on the Radio Works website about not installing them in an inverted vee configuration.

Any idea how much it would cost to have 3 telephone poles installed? And will they need to be guyed since the antenna won't provide the support that the normal wires would?

73,
Mark

Dick Carroll wrote:
"Ask the people of Homestead, Florida, many of whom sat for a week before they ever saw or heard from any relief person whatever."

Ham radio and Morse code had relevance? The victims` plight was unknown? There was an Air Force base at Homestead. The Air Force immediately investigated and reported in the aftermath.

There was a sheriff. There were police. There was a fire department. There is a Florida National Guard. There is a Red Cross. Washington has a FEMA and the armed forces to send in when necessary.

If the people of Homestead were without relief for a week after Hurricane Andrew, it wasn`t because their plight was unknown. There would have been little amateur radio could have done to speed aid to the victims.

In situations such as Andrew, the media immediately publicize the situation. Elected officials respond to send needed help as quickly as possible so that they will be perceived as being effective. Electrical power companies and communications companies send crews from many states to restore services as quickly as they can. These guys have their own radios. Hams are mostly superfluous.

Get a grip on reality and the 21st century.

Best regards, Richard Harrison, KB5WZI

Both are 1/2 wave antennas, If the J-Pole is made correctly,
both should work equally well, at least to start with.
How long they last, depends on how long it take one of the
many connections to corrode.

The transceiver puts 12v on the co-ax shield to power the electric
motor in the antenna. You will need a -good- ground between them.
Or you can do what I did and trade it in for some Isotrons (for base
use of course). I was trying to use it at home and it just did not
work. The Isotrons, 80/40 and 20/15/10 work great without a ground.
Of course if you are working mobile they would cause a -lot- of wind
drag. 8-) 73 Gary N9ZSV

Jerry
K4KWH

Nope, once I put the suppressors in it didn't. BUT, then again, I'm not operating mobile from my Ford - I'm pulling a 12,000 lb fifth wheel with it so "fuel pump talk" is a moot point. Regards, Jim R.

4186. Comet CA-UHV coil problems

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-05 16:59:32 UTC
From: Adam Adkins <km5nNoSpam@earthlink.net>
Message-ID: <MPG.150d81f9a7919aff989681@news.earthlink.net>
Source record: 169209

I have been having some problems with the coils on my CA-UHV that
I would like to get an opinion about.

The 15 and 17 meter coils initially worked just fine when I
installed them, but now both of them show sky high SWR regardless of what
I do with the tuning whips. I have cleaned up both the antenna and the
inside of the mounting brackets on the coils with fine sandpaper. The
antenna itself is grounding well to the body / chassis of the vehicle.
There is good continuity throughout the coils. I have not yet checked
the resonant frequency of the coils themselves (grid dipper decided to
quit working).
The 20 meter coil works fine, as long as there is no rain. If it
gets wet, the resonant frequency drops by about 60 kHz, making 20 pretty
much unusable until it dries out again.
The 40 and 10 meter coils work fine all the time. Never a problem
with them at any time, wet or dry. Likewise, 2 and 6 meters always work
very well (though there are no coils for these).

I contacted Comet, and their response was less than impressive.
"Might the the base coil," they said. "Send it in and we'll check it
out." If worse comes to worse I will do that, but I would rather have a
solution without having to go antenna-less on my car for the several
weeks it would require.

Has anyone heard of these problems before? Any suggestions? I
really want to put the 15 meter coil back on, now that 10 is starting to
fade.

Thanks!

73,

Adam, KM5N

I have a Tripp Lite "Omnipower" 1200 watts UPS (Uninterruptible Power Supply) which is an AC(120VAC) to 12 VDC back to AC converter. I used it for my business computer systems for many years. It has been sitting unused for about 5 years without the self contained 12 volt battery in it. It weighs about 25-30 pounds without the battery(don't have the battery). It is available to anyone who is interested FREE but you have to pick it up or arrange for shipping. I don't have the manual but the company is very much still in business. This is a quite sophisticated device and worked very well last time it was operational.

I am in Boise, Idaho

4192. Vertical (hidden if possible)

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-05 18:21:17 UTC
From: Hans Kaper <hanskap@kaper-1.tmfweb.nl>
Message-ID: <980lnq$m20$1@cyan.nl.gxn.net>
Source record: 169216

Hello,

Is there somebody who can advice me about a vertical antenna
if possible hidden "in" a tree?
I think about a vertical for 20 meters, which will be about 10 meters
tall. (Half wave) I'll need buried radials, at least 12, preferably more,
5 meters long or longer each.
My neighbours don't fancy antennas so I might consider erecting it
alongside a tree to hide it more or less.
I need advice about the effect. Would the antenna work better if it
stood "alone" and if so, how much do I loose when I hide it
alongside the tree?
They can't forbid me erecting the antenna, our constitution guarantees
freedom of collecting information from all over the world. (Free
translation) But if possible I will be kind to my neighbours.

Thanks in advance,

Hans Kaper PA3HGM

If you already have the Ringo, put it up. I would not buy the basic Ringo.
The J-Pole may not perform quite as well, but not enough to matter. Now the
more expensive models do perform much better.

Hans,
Sure, it will work. How well it will work is
another matter. It would be much better if it
were away from any near by objects.
Instead of 10 meters tall (1/2w), make it 5
meters tall (1/4w), same as the radials. If you
do try an antenna like this, I would be very
interested in how it works, let us know...

Mark,
I'd recomend you to start checking prices at local
lumber-yards. Prices vary greatly, and it just depends
on where you are. Same for the telephone poles, except
more so! Where I live, T-poles are going for about
$1.50 - $3.00 per foot (not cheap!), then delivery is
up to you. Ever tried moving a 50' T-pole? The one
person locally who has a dolly to move poles charges
the same as the cost of a T-pole, so it's like puting
up a tower as far as $$ goes. Good luck...
'Doc

4197. Antenna lightening protection

I've got a question for the group,

What do you guys use for antenna lightening protection? I have a rooftop antenna. Is it necessary to intall lightening protection? I always disconnect my radio when the storm approaches. What's the worst that can happen(without lighten protection)? What kind of system do you recommend? Is it going to affect the antenna performance? Thanks

4198. Vertical with 4 radials

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-05 21:05:40 UTC
From: W6RCecilA <Cecil.A.Moore@IEEE.org>
Message-ID: <3AA3FFA4.7A18F922@IEEE.org>
Source record: 169272

Somewhere I saw a chart of gain VS height of radials.
Does anybody know where I might have seen it? Was it
on this newsgroup? thanks

I use a 132 ft. dipole with 450 ohm ladder line but 300 is fine.
Either way you have to use a tuner as you know. You can look in any
Ham magazine and find several sources for 450 ohm line also.
Good luck. 73 de K2ES

1) A good healthy ground

2) Yes.

3) Burn down your house

You need to get a good ground up to the mast or whatever you have for your antenna support. It should not be bent in sharp angles as you work it down to your ground rod(s). Multiple ground rods in a grid is probably the best protection, creating a ground "window".

As to antenna performance, you may actually improve it.

4201. Re: Comet CA-UHV coil problems

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-05 21:39:56 UTC
From: jimmy john <jj@sandwitch.org>
Message-ID: <4A8A59F2BDCDD311BFC800508BA36AC807819FBD@www.premiersi.com>
Source record: 169277

Once the antenna is dry and working well, try to isolate the problem by
squirting water (maybe a weak water/detergent mix) just on the coil(s), to
see if that is where the problem is. Might be moisture into someplace else
than the coils. Careful aquirting might help you figure out if it is the
sides or ends of the coil, if that is where the problem lies.

Message-ID: <3aa40a33$0$45996$bbae4d71@news.net-link.net>
Source record: 169275

Try using "sky hooks" about 1 wavelength up. Seriously though--if no trees, you need to go the mast or tower route. For a decent mast, you could use irrigation pipe. Fair Radio has nice military masts for about $135.00 for the whole kit I believe. Not exactly portable by civilian standards, but once up should last quite a while. Use one, two, three or four of them (inverted V, dipole with center sagging, with center supported, or for horizontal loop, or 4 verticals).

You could even rig some sort of support on each end of your house using TV mast.

4203. golf ball retreaver antenna support

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-05 22:01:51 UTC
From: Rudy Marcelletti <rudym@net-link.net>
Message-ID: <3aa40cc4$0$46006$bbae4d71@news.net-link.net>
Source record: 169279

In my garage the other day and noticed my golf ball retriever in the corner. About 18 feet long extended and fairly stiff, yet collapses down to the length of a golf club. Mine is aluminum and has plastic joints so can't load it up. I think the fishing pole would be the better way, especially if you are going camping and plan on some fishing also, but if you already have a ball retriever, and it happens to be a fiberglass one.....I suppose it would work like a paint roller extender or light bulb changer pole.

Cecil,

In Orr and Cowan's book" Vertical Antennas" there is such a chart,
however, no mention is given where the figures came from.

Is your tv coax all RG-59/RG-6 style or is it 300ohm flat lead. If any of it is flat lead, replace it with the round style. Check all the cable connections and make sure they are good connections and tight. If any ends are frayed or coming apart, replace them.

Once that is done, i also agree to unplug the coax and see if it comes through with no antenna hookd up. Another good suggestion was to use a different antenna designed for the frequency you are transmitting on. Can you move it farther away from the tv coax. Is there a tv amp in the attic?

Smiley recognition or not, horizontal is almost always better than vertical. A dipole is better than an inverted V. A dipole is better than a sloper. A dipole is better than even the longest long-wire unless the long-wire is at a great height, is very long, and if the directionality that would result would not be a problem.

For HF, a dipole at least 1/2 wavelength above ground is almost always better than almost any other thing.

I'm old. From years of experience, I know this.

With a 300 ft feedline, you will loose what ever signal you gain by moving the tower to the higher place. Unless you use at least 7/8 inch hardline for vhf and maybe even larger lower loss coax for the higher freq's. You are looking at about 4-6 bucks a foot for it new.

Just put up the tower next to the house and invest in high gain antennas and the best coax you can afford.

Did you look at this site?
http://members.aol.com/k5oe/index.htm
It has some details of building the helix antenna.

4223. Wet Ladder Line

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-06 02:59:11 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <3aa44545_3@news1.prserv.net>
Source record: 169290

I have read that ladder line, when wet, has somewhat altered characteristics. I erected a 30m dipole recently, fed with about 110' of 450-ohm ladder line, and I use it on 30 - 12 meters. (My Dentron cannot seem to load it on 10m.) When the line is wet (rain or heavy condensation) the antenna is almost dead. Are moisture effects on ladder line usually this drastic? Does "real" open line have the same problem?

from his St. Louis Vertical kit?

4225. TenTec two-element antenna tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-06 03:02:52 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <3aa44623_3@news1.prserv.net>
Source record: 169291

I have been looking at the larger Tentec antenna tuner. It has two primary elements (coil and variable capacitor) and a switch to make several configurations from these two base elements. Most other current tuners use two capacitors and a coil. What are the pros and cons of these designs? I don't think I have ever seen a used Tentec tuner (this model) for sale. Does that mean that few people buy them, or that they are so good that no one sells them?

Okay ,but a longer antenna will lower the resonant frequency.
I could see hitting 10,11 and 12meters using a matcher but reception on
40meters
will suffer greatly. A matcher only fools the radio with a 50ohm load via
adjustable
capacitive/inductive circuit. It wont change the resonant frequency of your
antenna.

I'm not expert on 450 ohm twinlead feedline. With that
said - I have noticed that different tuner settings are
necessary whenever precipitation or dew is on the
feedline/antenna combo. However, I have not noticed a
quantifiable difference in how the antenna system performs.

The extra inches won't help much but you can buy extensions
to install under the whip. Hustler makes them and the Texas
Bugcatcher guy makes them.

The RS fiberglas whips were designed for 5 watts and the center
wire is very small. I don't know if it will take 100w or not.

Yep, it does. Ladder-line should be kept vertical and not run
horizontal where it can get wet. Mine comes vertically down
to the eave of my house and then runs horizontal under the eave
out of the rain. It's been very wet here in East Texas so far
this year but I have had very little detuning problems caused
by moisture.

If the input and output can be reversed, an L-network can tune most
antenna systems. Those switches are what allow the two components
to cover the necessary matching ranges. IMO, it's a good design.

One way to solve the problem is to use open-wire feedline for that
300ft run. Of course, that presents matching problems which will
need to be solved but can be as simple as a 12:1 balun on each end.
Sevick tells how to make 12:1 baluns.

Thanks for all the replies. If I get it correct, I need to connect the antenna ground to a ground rod. What about the radiating element? There must be electric charge buildup on the radiating elemnent as well. As I found out, the antenna mast is coated with an insulating paint. So I need to ground the mast separately as well, right?

Thanks

I feed my low band antenna with window wire. In snow, ice, and rain all I
notice is that the tuner settings change a bit.

George, KG4LBP wrote:
"A matcher only fools the radio with a 50-ohm load via capacitive/inductive circuit. It won`t change the resonant frequency of your antenna."

It is true that nearly all antennas have resonances which depend on their sizes. At an antenna`s resonant frequencies, its capacitance and inductance are balanced, producing zero net reactance, and its impedance is is a pure resistance. Maximum power transfer from the feedline to the antenna requires zero net reactance and a resistance match between the feedline and the antenna.

Often we need to use the antenna at a frequency it isn`t cut for, or in other words, off-resonance. The antenna may or may not have the same resistance as the feedline off-resonance, but for sure it will present a reactance. The reactance will stand in the way of getting the most current into the antenna. It needs to be neutralized with the opposite kind of reactance to get the maximum out of the antenna.

Our tuner/matcher needs to supply the complimentary reactance needed for a net zero reactance at the antenna`s feedpoint. This reactance provision is in addition to performing a resistance transformation if needed between the antenna and feedline. The resistance has to look the same in both directions for a bumpless transfer between feedline and antenna.

When our tuner/matcher has produced a zero reactance at the antenna, we may consider the external reactance as having retuned the antenna to resonance at the desired operating frequency. It all depends on how you look at the antenna as to whether its resonant frequency has been changed by the external reactance added by the tuner/matcher, or by the reactance of certain lengths of transmission lines of certain impedances.

Best regards, Richard Harrison, KB5WZI

I haven't seen that one here. I have seen one in the Orr books that estimates the number of radials at a certain height needed to equal 120 on the ground. It uses a graph. But to me, stating a certain gain increase or decrease just by the height of the antenna could be haphazard at best. I usually rate an antenna with it's free space gain regardless of height. To find out the effects of height over ground, I think modeling is better as you can specify the ground conditions etc.

In rare cases. Usually in dry winter weather. Thats almost unheard of
here in Houston. The only static you'll have to worry about here is
lightning. The ground doesn't mean anything unless you suppress the
feedline with a gas tube etc to ground. Just being grounded in itself
wouldn't help you as far as static charges if you don't use a suppressor
before the rig. MK

You would use a coax suppressor before the rig, which connects to your ground. Myself, I don't use anything. I just unhook when stormy and ground all coaxes to ground outside. My mast is well grounded which is probably the most important part. It all starts there. If you don't direct the strike to ground at that point with a low resistance connection, everything else you do will be a waste of time. So you want a good fat ground wire running from the base "ground" of the antenna going to a good ground connection below with no sharp turns or bends. An 8 ft ground rod at that point would be a minimum. One thing about trying to suppress currents from lightning..If you are not willing to do the WHOLE shack with suppressors on every wire going in and out, antenna, power, phone, etc, etc, I think you are better off just unhooking during storms. Just suppressing the antenna, and leaving the rest open is worse than no protection at all I think. I'd rather unhook the whole shack from the outside world otherwise. I've taken a direct hit with all grounded out outside and had no problems. So the cheapest way out will work as long as you unhook everything and ground all coaxes to a good ground outside. Also all grounds outside should be tied together. You don't want seperate grounds at different potentials. MK

When I was in college, I built the 40 foot mast of 3 20 foot 2x4's which
even
then had been in the ARRL Antenna Book for years. Worked fine; just make
sure you guy it well; it isn't self supporting!

Another cheap solution is irrigation tubing. The advantage is that you can
go higher with it. On my web site: www.karlquist.com I show a 90 foot
irrigation tubing vertical. I have also hung inverted vees at 60 and 90
feet
from irrigation tubing. You can sometimes get the irrigation tubing for
nothing
or almost nothing.

I couldn't imagine going to the trouble of telephone poles!

I don't think I'll ever sell my old drakes. I have an old R4 that is serial#0058. It's getting to be a collectable. But the xmtr a T4XB. Not quite as old. Also have a 2c and 2cq. Probably never sell any of them. Doubt I could get enough for them to be worth it. The 830 is a good old rig, and still pretty high performance, but I'm not as attached to it as much as the drakes, as I haven't had it near as long. After using the new 706 for a while, I'm tempted to sell the TS-830 and the VFO-230 and apply to a IC-746. But, dunno...The 746 may not be any better as far as basic radio performance. The 830 is still the best HF recvr I have in here right now as far as hard core performance and filtering etc. But I like zip zapping around with the 706. I've been using it today copying ACARS. Also got the selcal decoder going with it for HF. I do alot of aviation listening, both HF and VHF. MK

Overall, I agree with most of what you say, but still is apples to oranges. It all depends where you are going to talk, on what band, and at what time of day, as which is best. For regional 40m in the day, sure, everything you say will usually prove to be true, but if you work VK land on the same band 12 hours later, a good vertical will almost always beat the dipole. Doesn't mean either one is better. Just applying the best of each to a particular need. I used to run both on 40m at night. The dipole NEVER won overseas. Not even once. And it had the most theoretical gain. But the dipole hardly ever lost in the daytime, or to medium distances under 800-1000 miles. MK

It would probably help this discussion if cf told us what he had in mind. Somewhere I have the feeling that he got onto one of those mobile base coils that adjusts all over creation. They did indeed use 108" whips, pretty standard in the pre-CB days.

My guess is that 102 would be equally inefficient.

Rainwater is a fairly low-loss material. It also has a high
dielectric constant.

But a twin transmission line is not immersed in it. At worst the
line has a temporary thin surface layer of water.

In a tropical downpour line impedance Zo decreases by a few
percent. Propagation velocity also decreases by a few percent. Ice
and dry snow has similar effects.

It is necessary only to re-tune the ATU by a small amount. No need
to be concerned until steam rises from the line.

"Real" open line is affected to an even smaller extent because the
wettable surface area of spacing rods is much less.

There is a nice design for a three band vertical using rotor cable as radials in one of W6SAI's books. He used wood as a support. I've used PVC pipe painted with gren and brown "camoflage" paint. Works very well, even though it is hanging from a tree limb with the top at about 25-30 feet.

I've used four radials made of three conductor rotor line, one wire of each line cut for a quarter wave on 10,15 and 20m.

Good Luck,

Bill, W4WNT

Smiley recognition or not, horizontal is almost always better than
vertical. A dipole is better than an inverted V. A dipole is better than a
sloper. A dipole is better than even the longest long-wire
unless the long-wire is at a great height, is very long, and if the
directionality that would result would not be a problem.

For HF, a dipole at least 1/2 wavelength above ground is almost always
better than almost any other thing.

I'm old. From years of experience, I know this.

Alan

Alan: are you Cecil's long lost brother or what? You've been reading too many antenna books for too long (you said you were old, remember) and have forgotten the essence of systems engineering - understand the requirements first, then design a solution. I'm focused (with an additional apology to Cecil for not espying his smiley face AND its intent) on the requirements here. So, your "dipole-better-than-vertical" gyrations fall on deaf ears, especially when you state "almost always better." What part of systems engineering does "almost always better" play in understanding requirements and designing or purchasing a solution?

Sorry, Buds. The thread started out looking for a vertical antenna solution because the individual was horizontally challenged. I return to that basis each time because it makes my case for understanding the requirements first. PLUS, it allows me an opportunity to crack on Cecil who's the first one to jump on the dipole-better-than-vertical bandwagon, with you close in pursuit - : -) - or something like that. How'd I do, Cecil?

Regards to all (and I love these threads - gives me a chance to learn, smiley face(s) and all! Jim R.

Mark Keith wrote:
"I used to run both (a good vertical and a horizontal dipole) on 40m at night. The dipole NEVER won overseas."

Suspect the dipole was not in the clear and up at least 66 feet, which is 1/2-wave at 40m.

Mark lives in a high soil conductivity area. High soil conductivity helps vertical antennas but actually hurts low-angle radiation from low horizontal antennas.

The efficiency of a vertical over lossy ground suffers dramatically by comparison with a horizontal dipole. an elaborate ground system is needed with the vertical but not with the horizontal. The reflection from the ground is of reversed polarity and cancels low-angle radiation from a low horizontal dipole. So, poor soil conductivity is better for low horizontal antennas. Better to lose signal in ground loss than to have it reflected in reversed polarity and cancel the direct DX radiation you want.

For a comparison between the radiation of a 1/2-wave vertical dipole with its center 1/2-wave over ground, and the radiation of a 1/2-wave horizontal dipole, 1/2-wave over ground, see: Fig 4(A) on page 3-5 of the 19th edition of the ARRL Antenna Book.

The solid outline of the big signal is for the horizontal antenna. The dashed outline of the puny signal is for the vertical antenna. Both antennas are over "average ground".

Best regards, Richard Harrison, KB5WZI

Mark Keith wrote:
> To find out the effects of height over ground, I
> think modeling is better as you can specify the ground conditions etc.

For what it's worth, I modeled a 1/4WL vertical with four 1/4WL
horizontal radials using EZNEC. Here's the height of the radials,
gain in dBi, and take-off angle. 10 -.09@22deg, 20 .06@18deg,
25 .08@17deg, 30 .06@16deg, 40 -.13@15deg Note that from one ft
to 40ft the gain is maximum at 25ft for a 40m vertical.

Drooping the radials down at 45deg from a height of 25ft yielded
a gain of .23@20deg. Adding another identical array 1/4WL away
and feeding it at 90deg gave the expected cardioid pattern with
a gain of about 3dBi.

If Hans wants a "stealth" antenna, the radials should be on/in the
ground where they will not be seen.

Coming up is a great time to do this: when the grass is beginning to
grow, cut it extremely short and lay some radial wires - as many and as
long as you can - down on the ground. Fasten the wires down with
"hairpins" made from heavy wire, so they will not interfere with the
mower blades at normal height. By mid-summer, the grass will have fully
grown back and the wires will be completely covered - so much so, they
will be hard to pull up. (Statutory warning: "Your Backyard and Climate
May Vary", but it's OK for where Hans lives.)

Actually a half-wave vertical for 20m will not benefit much from radials, because the ground losses occur too far out for practical-length radials to help. A simple ground spike would probably be OK for 20m. However, adding some radials will make the same antenna very useful on 30m and 40m.

Sorry I can't comment on the effects of trees (it would be nice to have some here) but if you can space a thin black or dark green wire away from the tree it will be almost invisible to the neighbours.

Ditto that--102" stainless whip and 6" spring on a ball gives the 108" you are looking for. I have this setup mounted on top of a Suburban and hits a lot of stuff at speed--low wires, limbs, traffic lights and bridges. Hit scrapes the roofs at gas stations and banks. The whip is just very slightly bent near the top. Fiberglass will not hold up to this abuse. I use an Icom AH-4 antenna coupler that tunes 40 to 6 meters with this whip. Be advised there are much better antenna systems out there, but they WILL NOT take the abuse that a stainless whip and spring will. Even my SGC whip antenna will not take this abuse and that is why I mount that on the left side of the vehicle (center of the road has less over head obstructions) and about 2 feet lower than the stainless whip. The SGC antenna performs better, but I will swap it out and put the stainless whip on if I am going to seriously abuse it, like go fast off road in woods. To improve performance of the stainless whip, add about 10 feet of fine wire (22 to 28 gauge) with a gator clip. Do this at night because it looks goofy. Be sure you are in motion when you key up!

Ditto that--102" stainless whip and 6" spring on a ball gives the 108" you are looking for. I have this setup mounted on top of a Suburban and hits a lot of stuff at speed--low wires, limbs, traffic lights and bridges. Hit scrapes the roofs at gas stations and banks. The whip is just very slightly bent near the top. Fiberglass will not hold up to this abuse. I use an Icom AH-4 antenna coupler that tunes 40 to 6 meters with this whip. Be advised there are much better antenna systems out there, but they WILL NOT take the abuse that a stainless whip and spring will. Even my SGC whip antenna will not take this abuse and that is why I mount that on the left side of the vehicle (center of the road has less over head obstructions) and about 2 feet lower than the stainless whip. The SGC antenna performs better, but I will swap it out and put the stainless whip on if I am going to seriously abuse it, like go fast off road in woods. To improve performance of the stainless whip, add about 10 feet of fine wire (22 to 28 gauge) with a gator clip. Do this at night because it looks goofy. Be sure you are in motion when you key up!

Mark Keith, NM5K wrote:
"Also all grounds outside should be tied together."

That is required by the National Electrical Code. So, it`s good advice. Many jurisdictions incorporate the NEC into their ordinances. It`s sensible too, to connect your antenna ground to the same service entrance ground connection spot used by the electric company and telephone company. Don`t make the ground connection in the service center box as you don`t want the common impedance of the wire between the box and the ground rod or cold water pipe if that is the actual ground connection point.

The phone company uses the same grounding point as the electric company because they don`t want lightning bolts crashing between the phone and powerline connections inside your house. You don`t want flashes between your radio and the powerline connected equipment or the phone, either. So, use the same connecting point to ground that the companies use.

If you really must keep equipment surges low, put low-pass pi-net filters in every wire, including the neutral, supplying power to your equipment. I use tower lighting chokes as the series element to handle the equipment current requirements. Shunt the input and output capacitors of the pi-nets with MOV`s. Follow installation practices effective for interference suppression. Lightning is just big-time interference.

Best regards, Richard Harrison, KB5WZI

4273. Re: Wet Ladder Line

Newsgroup: rec.radio.amateur.antenna

Might be a tuner problem. I use 450 ladder line, about 150 feet or so, to feed a 160 meter dipole. I have the line twisted. The window line even goes through sever pine trees and rests on the limbs. I have used it in the rain and even with several inches of snow on it or with ice coatings. I do need to tweak the tuner setting some from usual dry conditions but that's it. MFJ-986 tuner. I have not found a frequency within the range of this tuner that I can't get "tuned" using the above antenna and a W9INN remote balun box and about 30 feet of RG-213 coax (I think--might be 9913F or plain RG-8--can't remember).

4274. Suitable vertical HF antenna info needed.....

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-06 16:15:47 UTC
From: nz8c@aol.com
Message-ID: <20010306111547.25771.00000010@ng-fw1.aol.com>
Source record: 169134

Hello!
I am trying to find a suitable HF antenna for my situation. I live in an apartment and can not put up any vertical over 20 feet tall. A dipole or any such wire antenna would be impossable to install up on the roof. I am mainly interested in working 10- 20m and maybe 40 and 80. I was looking at both the MFJ 1796 and the Hygain 18V and was wondering if they would work out OK. Has anyone used such antennas in my same sort of situation? How effective are they? Or is there a better antenna to choose? Please email me direct at: NZ8C@aol.com with any info.
Thanks!
73,
NZ8C

do a web search for that there is a website out there that tells you how to
build that antenna but i lost the URL so i cant help

Helmut Wabnig wrote:
"ARRL shows an illustration with a "feed wire" running from the helix end to the N connector on page 19-23."

In my book there is Fig 41 on page 19-25. It shows one of (4) tapered lines which raise the 140-ohm impedance of the helix to 208 ohms so that when connected in parallel the impedance will be 52 ohms at the N connector. If you can use a better antenna, why not exactly copy the ARRL 4-element array?

The problem with a line which tapers from 140 ohms down to 52 ohms is the tiny spacing at 52-ohms, especially when the tapered line is only one wire against a ground plane and not two wires. The spacing is only half what it would be for two wires.

If you want to transform 140 ohms down to 52, go ahead. In the same book, ARRL has tapered line information on page 26-6. In (Eq 8) the Zo and S-distance are halved.

Best regards, Richard Harrison, KB5WZI

4277. Helical whip with auto tuner?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-06 17:27:02 UTC
From: W7TRX <w7trx@mindspring.com>
Message-ID: <9836mfhcd1@slb7.atl.mindspring.net>
Source record: 169144

Greetings,

I am considering installing an autotuner (AH-4) in my vehicle to allow multiband tuning of a fixed length whip. I realize there are other antenna solutions that are more efficient (screwdriver, bugcatcher, etc) but for my specific purposes, the positives of this configuration may out weigh the negatives. I am not going to detail my personal needs in this forum.

I understand that an 102" stainless whip is likely the poorest antenna that can be tuned by the AH-4. SGC uses a dual, helically wound fiberglass whip that has two separate resonances . The Icom whip appears to be just a stainless whip, but it may have some base loading(not sure).

I was trying to determine the best antenna to use with an autotuner. This is also helpful for me to have a better understanding of different antenna configurations. What is the best way to improve the efficiency of an autotuner configuration? (no flames or wise cracks needed).

Here are my brainstorms...

Idea #1)
I am considering homebrewing a helically wound whip, with a top hat. I was considering stripping down a 7 foot fiberglass Firestick whip. Then rewinding with one or two lengths (ala SGC) of insulated copper wire for the antenna. The top of these Firestick's have a brass screw for tuning. This would make attachment of a top hat very simple.

Should I just wind as much wire on the whip as possible?

Is there advantage to wider spaced winding at the bottom, with closer spaced winding at the top?

Is a top hat of any real benefit to this configuration.?

Idea #2)
Installing a hamstick style antenna, let the tuner do it's thing, and seeing how well it loads up on multiple bands. (Which band hamstick?). Since these are resonant antennas I was not sure how well they would load up on other bands. I was just brain storming and thought using an 80m whip (it has the most wire) and trying it on the higher bands. Maybe adding a longer stinger so it is no longer resonant in the ham bands?

Idea #3)
Adding a Hustler mast to the bottom of a hamstick for additional physical length? (approx 12 feet).

Idea #4)
I just picked up a 10m hamstick style antenna from Iron Horse. The base and

stinger end both have 3/8x24 threads. This allows me to unscrew the stinger assembly from one antenna, then in it's place, install another full hamstick antenna. This provides additional overall length (12 feet) as well additional helical windings (2 hamstick base sections).

Any other autotuner antennas?

Your sincere input is very much appreciated.

Tracy, W7TRX

Might be a tuner problem. I use 450 ladder line, about 150 feet or so, to feed a 160 meter dipole. I have the line twisted. The window line even goes through sever pine trees and rests on the limbs. I have used it in the rain and even with several inches of snow on it or with ice coatings. I do need to tweak the tuner setting some from usual dry conditions but that's it. MFJ-986 tuner. I have not found a frequency within the range of this tuner that I can't get "tuned" using the above antenna and a W9INN remote balun box and about 30 feet of RG-213 coax (I think--might be 9913F or plain RG-8--can't remember).

Hans, why not involve them in the decision? Take them two drawings, one of a commercial vertical on a rooftop and another of a multi-band yagi atop a 30-metre tower, and ask them which of the two they would rather have in their neighborhood.

Also, point out the benefits of having an amateur radio operator in the neighborhood should a disaster occur.

Sure will do that.
Rothammels Antennenbuch (my antenna-bible)
says it should be 1/2w plus buried radials. You
describe what we call a ground plane which is 1/4w,
elevated and 3 radials under 45 degrees with
horizon (or 135 degr. to vertical) I use a GP to
talk on 2 meters via the repeater.

Looking to save $$ and build some type of HF mobile antenna.
Looking for 20/40/80m only, anything else is a bonus. I've seen
hamsticks and the likes, (yes they are not expensive) but i'd prefer
a single antenna rather than a collection sitting in my trunk. Screwdriver
antennas looks interesting, but i don't want to spend the $$.... any
good plans available? I'd prefer something that i can mag-mount
for easy removal.

Guess they will detest both. But on top of that, a 30 meter tower is too
expensive so there wil be no choosing.

>

Our country (Netherlands) is too small for a full size disaster. The last
disaster we had was in 1953. Flooding of Zeeland, a province of the
Newtherlands. All "disasters" since may well be covered with
hand phones (How do you call those in English?)

My Ten-Tec Model 238 tuner is not for sale - I bought it used in 1990! No problems with false resonances - there is only one setting for minimum SWR. Also works over a wide frequency range, including 160 meters to a limited degree.

A while ago I posted a reference to a simulation:
http://www.arising.com.au/people/Holland/Ralph/shortvert.htm
Might that be what you remember?

Truth in lending: others in this newsgroup questioned the
validity of the simulation. I have no reason to doubt them.

Cell phones.

A couple other ideas for you

The ARRL has a book titled "Vertical Antenna Classics". I recall it being not very expensive. You can probably buy it from their web site.

Also one of the antenna vendors advertises an antenna and tripod suitable for use in the back yard or garden. I'm having a senior moment - don't remember their name.

Thats a good point.It was in the clear, but closer to 1/4 wave up than 1/2 wave. The ground plane I was using was at the same height. But even if I had the dipole at 1/2 wave up, and kept the GP at 1/4 wl up, I still think the vertical would have won. After all, in order for the dipole to win in such a case to say VK land, the signal from the dipole would have to increase to them over 4 s units. How much gain this equates to I dunno. Doesn't really matter. It's not the gain that does the trick, it's the pattern.Everyone knows a dipole has more free space gain than a 1/4 wl GP. I don't think raising the dipole up to 66 ft would have made it the winner. Maybe much closer, but I think the GP still would have won out. I just don't see the dipole gaining four S units to VK just from raising another 30 ft. I may be wrong, But I kinda doubt it.

I don't see that in mine. I have the 16th edition.
>
> The solid outline of the big signal is for the horizontal antenna. The

> antennas are over "average ground".

This doesn't really make sense at all to me. How can a 1/2 wave vertical at 1/2 wave high have a puny signal compared to the same antenna horizontal? On many tests on 10m antennas I've never seen this to be the case in the real world. Both are relatively clear from the ground. In the real world, I don't think there is much difference in efficiency between the two, just different patterns. Actually, a 1/2 up is not a very good height to mount a vertical for many of the same reasons you state for the low dipole. Not in efficiency per say, but pattern wise. A vertical at 1/2 wave up shows quite a bit higher angle radiation than one at 1/4 wl up. But lets take 10m as an example..At my average height of 35-40 ft up, which would be over a wavelength high, I see very little

difference between a horizontal or vertical 1/2 wave in apparent efficiency. Only the pattern makes a big change. I know from real world use, I'd rather have the vertical anyday. Not because it's any more efficient, but it puts the power where I want it. Mostly at low angles with the null overhead instead of off to both sides. I've got a 10m 1/2 vertical at 20 ft right now. I'd be willing to bet if I mounted a horizontal dipole at the same 20 ft, it wouldn't be any better. Likely worse to many people I bet. My point is not to really claim either type as better, but rather use the type that fits the need. There are times when a dipole is the way to go. But there are also times when the vertical is the logical choice. Just depends on what you want to do. It's the "verticals always lose" comments that get me going. I know from my experience this is just not the case. But then on the other hand, if you are going to use a vertical, use a REAL vertical properly mounted. Not a 350$ piece of junk with an improper radial system. I always have good results with verticals because I never compromise on construction, size, or radial systems. Or at least if I do, I don't blame it on the antenna if it doesn't work to expectations. This is the case with 75% of the people that downplay verticals. They say they don't work, because they refuse to do the work needed to make one work properly. I've never spent a dime on an HF vertical. I build them myself. But all mine were still full size, with proper radial systems that likely would outdo the "average" setup by a large magnitude. I once compared my full size 32 ft radiator with a hustler multiband vertical. What a joke the hustler was...A dummy load on a stick. Totally useless as far as my vertical standards go. I bet my 8 ft mobile antenna was better or at least equal in performance. And your right, the good ground here doesn't hurt things either, but I still designed mine to have a radial system that could be used over poor ground and still do well. I say, use both types. They both have their place. It's fun to switch back and forth and see the differences. I noticed alot of weird things about propogation on 40m at night doing this. MK

Hummm, I think even modeling can be deceptive sometimes. I know in the real world, 36 ft up was better than 25 ft up. I've noticed comparing dipoles and verticals with modeling that the results can skew towards the dipole in many cases. The real world performance didn't really agree too much unless I set the ground cdx for the vertical as "VG". I noticed when I modeled my 40m GP using "average" ground cdx the results didn't match the real world results at all when comparing against a dipole at the same height. I did notice when upping the GP height to 1/2 wl up, the pattern went all to heck. I'm not sure if this is quite a drastic in the real world or not. I've never been able to run a 40m GP at 66 ft to try. I do know from the real world, and eznec seems to confirm, a 1/4 wl up is a real nice height for a 40m GP. 25 ft is ok, but I'd rather be at 36 ft regardless of what the modeling says. I know from the real world results, the higher one did a bit better. MK

On fiberglass whips,

Something in a 96" model some of you may wish to
consider/try. The Francis CB-28 Wheeler Dealer or
the CB-50 Amazer. If the 96" will work for your
particular set-up I heartily recommend the CB-50.

One other point...I don't know if the decrease in performance from lowering to 25 ft from 36 ft, was due to the extra ground losses, or the pattern changes. I suspect the ground loss, being as I only used 4 radials. MK

The 19th edition (last year's) of the ARRL Antenna Book shows, on page 22-4, an A-Frame mast made of three 2"x2"s, each 22' long, for a height of just over 40'. Requires 3 guy wires. Looks like a relatively inexpensive weekend project with lumber you can get at any yard.

Also, my 2001 Radio Shack catalog shows a 36-foot telescoping, guyed metal mast at $70.

I've found no reason to make it an A-frame for a fixed installation.
I use 2x4s in a 4x4 configuration for the first 26 ft and then use
a 20ft piece of 1.25" fiberglas for the next 16ft. I use treated lumber
and dig a 3ft hole for the 4x4.

Cecil,

Thanks for the "hands-on" data. To get those results on 40m-10m from a 12ft whip is great news.

What was the mounting location on your vehicle? I know the middle of the roof is ideal, but a 12ft whip up top is going to get whacked!!! If this kind of performance can be achieved with a bumper or rear side panel mount that would be ideal for my needs.

Also what was the source of your 12ft whip? I planned on trying a 102" whip with a Hustler mast.

Thanks, Tracy

Hey, Dick,

You just reminded me of something. Speaking of "base coils" that adjust all over creation, I have one of those ancient Bay Mobile antennas that was the fore runner of the Webster Bandspanner. It has the 1 1/2" base coil with a 102" whip that slides in and out to resonate on frequency. I found it at a local hamfest (Charlotte, NC) for 10 bucks. I just bought it for nostalgia and, mostly, it hangs on a rack in the garage. It's not very efficient, of course, but I suppose in its time, it was considered "neat". Musta been around 1950 or so? I have used it on 20-10 meters and it works pretty fair. Seventy five sucks! Just for kicks, I once pondered a way to move it up and down like a screwdriver. NAH! Not worth the trouble. Still, it's in excellent condition and, I suppose, it spent quite a few years in someone's barn judging from the lack of wear--even the whip isn't bent.

I once loaned it to a friend and he broke it! But, being a machinist, he repaired it good as new (or even better)! Can't tell it was ever damaged and it works as ever--which was never all that good. LOL!

If you ground the antenna mast, and the antenna is installed as instructions directed, then the static issue should not be a problem.

I guess my first post looked more like a for sale tittle, so the re-post. Ihave afriend gutted MFJ-968, someone burnt out the coil and cut out the balum and connection wires. I need a diagram on installing a junk box roller inductor. and use the split variable cap. We want to at least use the box and RF indicator and the cap, if we can

Steve,

There are as many solutions to this as liver pills in a bottle. One
way is to find a plastics supplier and have him machine you a coil
form from nylon or Delrin. Have him thread the circumference of the
form at 10 turns per inch and mill indentions at equal distances around
the form. This will allow you to tap the coil at various places for
different bands (not my favorite way, but it *does* work). Use #14
silverplate wire to wind the coil. Cost of coil and wire about $30.
Have the machinist bore thru the center and pipe thread each end for
a 1/2" X 1/8" brass bushing--common item in home and hardware stores for
less than $2 each. The threads inside this bushing are the same as the
3/8" X 24 TPI used on most masts and whips. You might want to "chase"
these threads with a 3/8" X 24 tap for good measure. Screw these into
the ends of this coil tightly. Wind the wire onto the form and secure
at each end with a stainless screw. This is to keep the wire tight and
allow for adjustment if needed. Then attach each end of the windings
to the coil. For your form, it depends on how large you want it--
2-3" dia works well at around 14" long for the 3" size. Stop your
windings about 1 1/2" from each end (you don't want the brass bushings
within the windings.

For a lower mast 3 or 4 ft long, buy 3/8" brass rod OR get some 3/4"
copper tubing and braze or rivet two of those same bushings.

There's a lot of ways to do this. I have made many loading coils this
way and they work very well--nothing beats a good center-loaded whip
for performance. You are only limited by your own imagination.

I don't think I'd go that route. You could get it to work well on the
lowest band, but the high bands likely wouldn't be too hot. I guess it
would be fairly easy to try though, say using a stock 80m hamstick etc.
>
> Is there advantage to wider spaced winding at the bottom, with closer spaced
> winding at the top?

In general, yes. I think the lower the frequency the more difference it
makes. What it amounts to is a normal whip with a narrow lumped coil
instead of the non varying pitch. The current distribution is improved
on the "lumped" type setup. Tne drawback can be increased losses due to
a tightly wound lumped coil. For the best performance, use thick wire,
and slightly seperate the windings. This is easy if you use insulated
wire. The insulation acts as a spacer for winding.

>
> Is a top hat of any real benefit to this configuration.?

Only on the lowest bands in general. I don't use a hat myself. Too much visual clutter, and windload for my lightweight antennas. I just try to use the longest stingers I can.

>
> Idea #2)

> most wire) and trying it on the higher bands. Maybe adding a longer stinger
> so it is no longer resonant in the ham bands?

This goes back to number #1. if you do this, it's best to use a higher band stick, and add longer stinger to it for lower bands. Lets say you have a 11m firestick that uses no real stinger. "Some are this way". This antenna works ok on 10 as is. It will work on all the lower bands down to 20m with a fairly short added stinger. On 20m, you would probably need about a 2-2.5 ft stinger to tune the 11m antenna to 20m. Each band, 17,15,12 would use an increasingly shorter stinger. Sure, you have to get out and switch, but at least you have a properly functioning antenna on each of these bands that will work well. A 20m stick can work 40m with about 3 more feet of stinger. Varies with the stick used. I have one 20m stick that works 20m with no stinger. "it's fairly lousy on 20m due to this fact. But with a 3 ft stinger it works 40m, and does it very well. I get S9 plus reports commonly with 100w radio around the state in the daytime.

>
> Idea #3)
> Adding a Hustler mast to the bottom of a hamstick for additional physical
> length? (approx 12 feet).

For a high band antennna this can make it way too long. On a low band antenna where the coil is on the upper section, the mast will make very little difference in resonant frequency. But, with it raising the coil up on the structure, it greatly increases efficiency. I have a 3 ft solid mast that I add to my normal 8-9 ft antenna when I'm parked. On 80m, I might only shift freq maybe 200 kc by adding this lower mast. But my efficiency takes a BIG jump. Well worth it for the low bands. I do it all the time.

>
> Idea #4)
> I just picked up a 10m hamstick style antenna from Iron Horse. The base and

> additional helical windings (2 hamstick base sections).

This can work. But use a long stinger on top of all that or it will be a mobile dummy load.
>
> Any other autotuner antennas?

My all band antenna is a 11m firestick that is 5 ft tall. I cut out the windings in the middle and added a 80m loading coil that is nearly 3 inches wide. I have a tap on this coil for 40m if needed. Now, with the basic antenna with a 2 inch stinger, and the coil bypassed with a jumper, I tune 10m. For each higher band up to 20m, I have a longer stinger. Appx 2 ft for 20m. All the rest shorter as you go up band. So we're workin 20-10 so far ... Now for 40m, I unhook the coil jumper, and hook it to the 40m tap, and add a almost 4 ft stinger. Viola! We're on 40m. With bugcatcher performance I might add due to the big coil. 80m, unhook the jumper and run the whole coil with the same 4 ft stinger. 80m with again, bugcatcher performance . Works all bands and weighs very little. No spring needed. No heavy mounting gear. Add the 3 ft solid mast under this for 80/40m when parked and you are really with the program. Actually , I've driven with it that way with no problems. But don't do it too often. I'm going to make a higher performance version of this all bander pretty soon. A bit taller and the coil higher up on the stick. For the present coil I used wide plastic tubing as the form. at each end I have a "plug" with a hole in the middle that lets the stick slide thru. I mount the coil on the stick, and glue it on so it won't move. I used #12 insulated house wire to wind the coil. Then the coil has a black plastic covering over this to match the rest of the stick. The antenna is all black. Looks like a black plastic coated bugcatcher sorta. MK

I'm looking for an article published in QST in what I thought was the summer of 1998 to use a specific Radio Shack TV antenna for 2 meters. I built the antenna and it works just great, but have been asked to do a presentation at the local club, and can't find the original article. I've searched the QST technical data base for a title but haven't located the article. Anybody happen to remember the article and could let me know the month and year? Certainly would be helpful.

The only thing I see in 1998 that might be it is in the January issue.
The article is, "A 2-Meter Phased Array Antenna." Didn't see anything
in 1997 or 1999.

4321. Re: Helical whip with auto tuner?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-07 01:40:24 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9843fkrek1@plutonium.btinternet.com>
Source record: 169092

A short (in terms of wavelength) helical HF antenna is VERY sharply resonant on a single 1/4-wave frequency only.

Use of an ATU, whether automatic or not, will permit the range of resonant frequencies to be pulled only a little, perhaps over some tens of kHz in the same band.

On other higher frequency bands, although an automatic tuner may indicate what it thinks is an impedance match, the helical antenna will be extremely inefficient. On higher frequencies the helical winding may be several lossy wavelengths long. If it radiates at all, everything will go straight up and perhaps straight through the ionosphere. An ATU cannot convert what is essentially a single-band antenna to a multiband job.

The situation is no different to trying to pull the frequency of a quartz crystal-controlled oscillator into another band by means of a tightly couple variable L+C network. Loss becomes so great the poor thing just stops oscillatiing before its been dragged, protesting, more than a few 100 kHz at most.

The AH-4 tuner manages OK at any frequency above 3.5 MHz with any (unloaded) antenna longer than some relatively short length. If you wan't to work 160 meter band with a 102" whip, there's nothing which can be done about it except to stop the car and, with the help of an aligator clip, attach an extra length of wire.

If you base-load the whip, or load it in any other way than with a top capacitance hat, then it reverts to a single-band antenna. It may, of course, work after a fashion on more than one band if you deliberately make the loading coil lossy.

A capacitance hat without a coil is the most efficient way of loading any short vertical. It will allow the tuner to operate OK at a lower frequency without increasing antenna height. On the other hand, at the lowest frequency most of the lost power will be used to heat up the tuner coils. So some judicious de-rating of the manufacturer's stated power handling ability may be in order.

If you have no great desire to work below 7 MHz you will very likely find the AH-4 and a 102" whip are an efficient multi-band combination. The AH-4 will behave exactly as a base-loading coil on all bands.

Richard, if you think turning one of your ears into a "black lump that resembled a piece of coal" was therapeutic, then working around "for years in the middle of an HF megawatt field" was certainly not that healthy (at least not when it comes to your mental health). ;-)

Mark Keith wrote:
"It`s the "verticals always lose" comments that get me going."

Of course verticals don`t always lose. Their biggest advantage is that they are non-directional. Hams often would like to contact stations from many directions. Most horizontal antennas of reasonable height favor some directions over others. In the lower frequency shortwave bands it is often impractical to rotate the horizontal antenna for best operation in all directions.

However, that is not how commercial h-f radio operates. Broadcasting and communications relay nearly always have well defined targets. Any energy not directed at a specific target is considered wasted. Omnidirectional antennas are just about excluded from commercial service.

Directional arrays use vertical polarization at low and medium radio frequencies. There are almost no vertical directional arrays used commercially for shortwave (higher frequencies).

RCA International Division Chief Engineer Ed Laport published an excellent book, "Radio Antenna Engineering", copyrighted in 1952, which covers all manner of antennas for use up to 30 MHz. He has 170 pages on h-f antennas. All of the shortwave antennas are horizontals. Why? Because that is what is used commercially. The reason commercial h-f point-to-point radio users and broadcasters use horizontal antennas for transmitting and receiving is simple. Horizontal antennas are the best shortwave bargain, unless you are operating over sea water or a salt marsh.

Best regards, Richard Harrison, KB5WZI

You may be a whiz at big rig engineering but it's clear you don't have
much of a grip on disasters nor the relief thereof.

First, all those police, firemen, sherrifs etc in the area are just as
much victims of a big breeze like Andrew as the rest of the populace.
Their homes, families, vehicles, radio towers, headquarters, and
powerlines are just as destroyed as any homeowners. Not to mention the
roads they use to get around.
The first fact any wide area planning group recognizes is that local
officialdom will be just as desperate for help as the general
population, at least that must be assumed at the outset. No one can
accurately predict just how any situation will develop, but it is simply
uninformed folly to assume that your tax dollars are sufficient, and
your elected officials are well enough informed, competent and have
access to the necessary resources to set into place expensive releif
mechanisms which, for the most part, will never be used. Mostly tax
money doesn't get spent for that sort of thing in the amounts necessary

to fully cover the event, or really even come close. Other priorities prevail.

If you think any of us believes that ham radio is about to "save the day" in any of this you are simply misinformed. Even good ol' CW won't do too much good. But if doesn't take much understanding to grasp the simple fact that whatever communications that still exists in a workable state will be useful in the extreme, and no one will care a whit that it is an amateur and not a professional doing the talking.

If I had lived in the middle of the Homestead mess I'd have soon had something on the air on some ham net frequency- yes, hams operate a variety of emergency relief and assistance nets when those things happen- so as to inform the relief agencies that yes, we had a problem, here is were we're located, and what we need immediately, or ASAP. If our needs are a priority, such as injury/infants/elderly/medicine, relievers can helicopter to us, when they can. The people who sat for a week waiting in the blind had to depend on a block-by-block canvas, where every block was a roadclearing operation, and they just happened to be many hundreds of blocks into the mess. Anyone who was in a critical situation there would have been out of luck with no way to call for help.

I know that ham radio, to you, will never be anything more than just a pleasant passtime, you've made that quite clear. What is odd is that after a long career in radio you still don't understand the value of radio communications-even ham radio communications.

Even the local NOAA meteorlogists state, rather forcefully, that ham radio storm spotters are a valauable part of their early warning operation, in spite of all the police, shriffs, firemen, and many other public employees about. Do you wonder why?

I fear your advice about "reality and the 21st century" is misdirected. 180 degrees out, in fact.

73, Dick W0EX

I am surprised that Wes hasn't commented on this thread thus far.

He had done a study which was published in the ARRL Antenna Compendium Vol. 6 on ladder line and gave measurement data that he made comparing the changes encountered when the line was wet. I suggest you check out his findings.

Several years ago I attempted to measure the so called 450 Ohm ladder line. I used a 75 foot section of new clean line and measured the line loss wet and dry. While my loss figures were different that those Wes had measured I did ascertain that, in my case, the wet line had double the amount of loss that when it was dry.

In applications were there is a very high amount of reactance on the line this additional loss can be substantial.

Michael Hart wrote:
"Both the designs I looked at cover from the 80m to 10m HF band and are similar length, if not smaller, than a normal 80m dipole."

Traveling wave antennas are usually defined as being one to eight wavelengths long. 80 meters is 262 feet.

What distinguishes a traveling wave antenna from a standing wave antenna is the reflected wave which produces a standing wave pattern on the standing wave antenna. The traveling wave antenna is terminated at its far end in a resistor equal to the characteristic resistance of the antenna to avoid a reflection. Rhombics, Beverages, and other long terminated wires are traveling wave antennas which favor the direction of the termination resistor.

Traveling wave antennas can`t be very efficient if they are shorter than 1/2-wavelength.

I don't see Tom Raush W8JI in here on this thread, he must be off
somewhere, or else he's just tired of saying it, but-

He's the guy who put up 300 foot towers so that he could have his
dipole *UP* in the clear, without any question whatever about it. And,
guess what- his verticals beat the socks off all his high dipoles.
Without question. His disappointment is palpable.

I assume that some folks have used such a combination and were satisfied with it. But I don't see how you could describe it as efficient. My own tests have shown it to be quite inefficient on 40 and 30m. True, the AH-4 acts as a base-loading coil, albeit a poor one. Maybe there's something wrong with my AH-4?

Try this test: Go to 40m and tune a 102" whip with the AH-4. Then see how long you can send a constant 50-60w carrier before components in the tuner heat up and the SWR rises to the point that the PA folds back. With my AH-4 on 40m it happens in less than 20 seconds. I get similar results on 30m. Even on 40m phone with the relatively low duty cycle of SSB I see the SWR creep up as something in the tuner heats up.

Is this atypical of AH-4 performance? I've always wondered if there was something wrong with my tuner. It will match a 102" whip on 40-10m, but operating CW on 40 and 30m with such a setup results in very poor performance compared to even a hamstick, notwithstanding the "rising SWR" problem.

I'd appreciate hearing from folks successfully using the above on 40-10m.

Perhaps he meant "self resonance." MFJ claims an exclusive feature on one of their tuners that keeps "damaging self-resonances away from your operating frequency." It works, too. I have an MFJ tuner on the shelf in the storage room and to my knowledge I've never had any damage due to a self-resonance.

>Why is only having one setting so good?
>
MFJ advertises it as a feature on one of their tuners. I think it's a great idea. If you have a tuner that gives minimum SWR at two or more settings then you have to decide which one to use, and there are enough decisions to make in life as it is.

Perhaps the loss is substantial under such conditions, but
what other feedline could one use with a dipole of fixed
size that must operate on ALL HF bands?

I am not aware of any other method of feeding such an
antenna that is anywhere near as efficient as 450 ohm
TWINLEAD.

There is much that I do not know when it comes to radio, but
I am always willing to learn.

I think he probably meant multiple match points. With a T-net tuner,
it is possible to find more than one match point setting. Some match
settings are more lossy than others. I don't think an L-net tuner
is capable of multiple match point settings.

Have you considered using parallel open line? It has lower losses when wet than the plastic covered window line.

Due to the fact that I live in a wet area and based upon the measurements I had made I choose to use open line for my situation.

A more fair comparison would be to use radials that are 1/4 wavelength long at each height, rather than in free space. When radials get close to the ground, their resonant length becomes shorter. And you'll find that if you get them too long, the efficiency drops. To determine the resonant length for a radial at a given height, model a dipole at that height and adjust its length for resonance. A resonant radial will be half that length. Efficiency decreases if the radials are made much longer than this length.

"First, all those police, firemen, sheriffs etc in the area are just as much victims of a big breeze like Andrew as the rest of the populace."

Yes, and they are running the show. Hurricanes don`t strike unannounced anymore. Weather satellites and other advanced warning systems notify the position and probabilities.

Evacuation of areas likely to flood is ordered. Some always stay, and some usually die in bad storms.

When the storm ends, the sheriff sets up roadblocks and restricts entry to avoid looting and injury from hazards left by the storm.

I`ve had to receive a group of injections before the sheriff would let me in to work on some of the storm caused problems. This was 40 years ago, but the same things happen today with access after a serious storm. Amateurs were only talking about the storm and the problems it left. Communications and alleviation were in professional hands.

Best regards, Richard Harrison, KB5WZI

: What is a "false resonance"?

: Why is only having one setting so good?

There are generally several inductor/capacitor combinations that will
provide the desired match.

You want to minimize the inductance used - as that reduces resistive
losses in the tuner.

The Radio Shack model shown in the July article is the 15-2163 FM
broadcast antenna. It's still listed in the latest catalog. Same
price.

Right.

For riot control, it isn't reasonable: Haven't any of the
Marines (or, whatever) who developed the idea seen a riot on TV?

The rioters pick up red-hot tear-gas bombs and throw them
back at the troops (Third-World substitutes for police).
So, pain has no obvious effect.

By the way, GOOGLE says this new idea in "weapons" belongs in the following groups:

alt.tv.x-files.creative, alt.religion.scientology,
alt.alien.visitors, or alt.paranet.ufo.

Who says filtering doesn't work!

I've heard that some folks periodically *wax* their window line
(so that it sheds the water). Living in the "high desert", I haven't
tried that. In a previous life in Washington State, I used real
open wire line, and weather had a negligible effect.

4352. Re: Helical whip with auto tuner?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-07 07:44:13 UTC
From: Mike <km6ab@pacbell.net>
Message-ID: <3AA5E6CD.48229BAF@pacbell.net>
Source record: 169026

I have use an SGC auto tuner with a 40m hamstick and found it to obviously work great on 40 but down in performance on other bands, especially 10m. Other users have mentioned that center loaded whips like the Valor don't seem to radiate well out of band with an autotuner. Continuous loaded helical whips seem to do much better as multi band antennas with an autotuner. I found 9ft cb whips work great on 20m thru 10m but are very poor on 40m and lower. The dual wound SGC whip works well and is nearly as good as the Hustler and Valor mono band whips I compared to. The 12ft whip helps a little on 40 and 80m but the SGC whip is still noticeably better. I have logged many 160m contacts from So. Cal to as far as Nebraska with the SGC whip. When I mention the antenna is an 8ft loaded whip the response is usually " yea, right...". When parked or camping I throw up a 16 or 32ft military whip which is outstanding on the lower bands. Wish I could use that in motion. The SGC system is a bit ugly, but a higher performance multi-band antenna is going to be bigger and uglier. Overall I will gladly pay the small sacrifice in performance for the convenience of instant QSY with the SGC tuner/whip.

I'm sure your intention was good, but if you go to the mcafee site
(the one your message references) and look under hoaxes you'll find
this message, and it's represented as a hoax. The text is only
slightly different. So what your friend sent you was possibly in
error. I make no judgement of him or you. However, there are a lot
of hoaxes as well as real viruses going around. You might go there
and check it out. It's interesting.

Just thought you'd like to know.

Tony

There I go again, forgetting that the rest of the world does
not have my physical limitations.

Yes, true ladder line, or open wire feedline, is more
efficient and will perform in a superior manner to 450 ohm
twinlead and I know it. I just forgot about it because of
the labor involved and my lack of ability to perform said
labor. Thanks for setting the record straight.

I have a chart I made for tuner settings with the ladder line dry and when it was pouring rain. I have a 135 ft doublet fed with about 150Ft of window line. On 40 to 160, the tuning doesn't vary that much from dry to wet. On 20 to 10M, I notice that when it is dry there is a very sharp tuning peak and an increase in the background noise of the receiver when peaking the tuner. When it is wet, there is no sharp increase in noise and a very broad peak when tuning for lowest SWR. My conclusion is that there is noticable loss on the higher bands when the line is wet, but on the lower frequencies there doesn't seem to be any noticable loss.

4365. Cushcraft MA5B diagnosis

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-07 15:45:35 UTC
From: Thomas Beltran <tbeltran@earthlink.net>
Message-ID: <zlsp6.4284$x4.449908@newsread2.prod.itd.earthlink.net>
Source record: 169039

I have a Cushcraft MA5B, which I put up this past December. I've been very happy with the antenna, and then a problem developed on ten meters: the SWR is now high (in the 4:1 range). The other bands work fine, and in fact, according to the RF-1, I have a wider bandwidth than the antenna specifications.

I contacted Cushcraft, and was told that I needed to determine the resonant frequency of the traps. They opined that one of the traps was bad. The resonant frequency of the traps should be about 1 mhz below the band frequency (for ten, the freq. should be 27 mhz.) I'm not really sure how to go about checking the trap.

I have an Autek RF-1, but the instructions show that one must actually insert the RF-1 into the circuit to check the trap, which would destroy the trap. Also, I would hate to have to buy equipment to check the antenna.

Does anyone have an idea about how I can check the traps? Cushcraft has agreed to replace the traps, but they want to know which one's are bad. I would appreciate any assistance. Tom W6EIJ

Tracy Brooks wrote:
"Where is the best place to find used ones (40 ft or more towers)?"

Local acquisition may be easier. Look in your yellow pages under "Towers-Communications". There are about two dozen listings in Houston.

Good towers are replaced when needs change and the new tower supplier often ends up with the old tower in his bone yard.

Many tower companies erect poles too, but if you are mounting a satellite dish, you need a guyed tower with either cross section or torque arms for stiffness to prevent twisting. I`m assuming you don`t want to spend a fortune for a really stiff self supporting tower.

But why put a satellite dish on a tower? Surely you can find an open space close to your house. Height means nothing to a satellite dish. Without a parabolic antenna, you can use a pole.

Best regards, Richard Harrison, KB5WZI

Hi all,

I'm interested in putting together a 3 element YAGI for 10 meters and one design I've found requires only a 12' boom length which would work nicely in my rather small lot.

Any suggestions for a good lightweight (and inexpensive) boom material that will stand up to the weather in the Midwest (ice storms, high winds, etc..)?

Email appreciated.

Thanks,

John

Another one I received a couple times is an email message with no address, no signature, no text, nothing except an attachment titled "Norton Antivirus Report". My Nortom antivirus program grabbed it, Id'ed it as a virus and quarantined it. It wouldn't be smart to open any attachments.

==========

Conclusion about loss on higher freqs is not entirely valid. Clean water is a low-loss material at HF.

Water has a high dielectric constant which decreases velocity factor. With water running along the feeder its length in wavelengths increases. The effect increases proportional to frequency. It is 15 times greater at 30 MHz than at 2 MHz. When standing waves exist on the feedline at 30 MHz the tuner may need considerable re-adjustment. Q and selectivity of mismatched ladderline are high and detuning may be obvious even on receive.

A smaller effect is again due to the high dielectric constant of water. Capacitance between the wires increases and Zo decreases according to the squareroot of C. Line loss in dB is proportional to wire loss resistance divided by Zo and so line loss increases - but only slightly.

Has anyone ever seen steam rising from 450-ohm ladder line ?

Reg

4373. CFA Update

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-07 20:06:43 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3AA694D3.46F1FBE@eznec.com>
Source record: 169047

The following message was recently posted elsewhere by Jack Belrose, VE2CV. It was intended mainly for broadcasters, but I'm sure readers of this group will be interested. Jack was kind enough to give his permission to post it here.

Roy Lewallen, W7EL

CFA Up-date

You have not heard from me for some time on this subject. I have been awaiting something to report.

MF Broadcasters are still maintaining an interest in CFA Antennas, in spite of what has been said/or not said about this antenna.

But Proof of Performance measured results outside Egypt are yet to be publicly released.

The LB Broadcast CFA program on The Isle of Man has suffered a set-back, with the denial of permission to build (environmental concerns).

Robert Richer's, of CFA, Ltd (USA), CFA project in Shropshire, England, is still waiting for Fathi Kabbary to perform his magical touches necessary to tune and test the CFA. Ben Dawson will (it is reported) carry out proof of performance measurements on this CFA.

The CFA Project in Santos, Brazil has come to a standstill. The performance of the antenna (on the roof of a building with a view on the skyline), after completing many mechanically related modifications asked for by Kabbary, including the addition of third cone (??) on its top, is still performing poorly [Sylvio Damiani, reported in the March 2001 issue of AntenneX] --- but no measured results reported.

The San Remo CFA, we had heard earlier that it was performing as expected, is apparently producing less signal than the previously used tower antenna at that location --- a "problem" attributed by Kabbary to surrounding high objects on all sides and very high trees to the north --- but again no measured results reported.

The CFA in Sidney, Australia is for sale (or will be purchased (back) by Kabarry ??), but it is still in use, tuned as a conventional electrically short monopole.

Meanwhile the FCC has finally granted Lawrence Behr Associates a license (WC2XKX) to test the CFA in the USA. These tests are authorized on three frequencies in North Carolina.

Finally a success (??) story. Brian Stewart has reported that the CFA in Barnis, Egypt proves that CFA antennas work, since this ground mounted CFA shows a high degree of efficiency --- but it should be noted (my comment) that a microwave relay tower stands in the near field, having a height that is close to a quarter wave on the frequency used.

The CFA story continues.

But the purpose of this Technical Correspondence (TC) is tell you that the papers presented at the IEEE BTS Symposium, Vienna, VA 27-29 September, 2000 are finally posted for reading.

The WEB site is:

http://www.eriinc.com/IEEE/

Note: IEEE in caps.

Concerning our experimental measured results, we have (finally) learned how to tune the antenna, tuned as a CFA (feed currents in quadrature, and transmitter SWR = 1:1). This has been achieved by using a storage oscilloscope so both current in amplitudes and phase can be viewed simultaneously.

Have fun reading.

Regards, Jack, VE2CV

Hi All,

Hmmm, it seems to me that the proponents of the CFA at one time
exclaimed that their "technology" employed the Earth's magnetic lines
of force to enable communication THROUGH obstacles such as mountains
and pyramids and so on.

And now to hear that some "very high trees" now obstruct a medium wave
signal evidences an extreme shortfall over the standard method. Trees
kill signal indeed! Obviously a greater challenge than mountains for
CFAs.... ... but then, there are no trees (to speak of) in Egypt and
no Pyramids (to speak of) in San Remo.

Well, as updates go - not so much up as lateral.

Roy, W7EL wrote:
"When radials get close to ground, their resonant length becomes shorter."

Arnold Bailey says in "TV and Other Receiving Antennas" that ground plane antennas on the ground have a 3 db advantage over those high above ground. Those on the ground get a boost because their radiation is confined to only one hemisphere, but when the ground plane is elevated it behaves more as a dipole and loses the gain from its image in the ground.
All of this is a function of elevation angle and how good a reflector the ground is.

Bes regards, Richard Harrison, KB5WZI

Regarding using the lest inductance to acheive the lowest loss, what about the shorted turns? If you use the least inductance, with a tapped inductor, either switch tapped or roller inductor, you have the greatest number of shorted turns which are inductively coupled to the rest (active part) of the inductor. Seems to me this might be lossy too. For this reason those Collins coils which wind the unused part of the inductor onto a conductive drum are really neat. ...Also the "false resonances" may not all be inefficient tunings that couple less power to the antenna output side of the tuner, some of those tunings may be self resonant tunings of the tuner wherein all of the power is resistively consumed in the tuner and none gets to the antenna feedline at all.

4378. Re: Boom material for short yagi?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-07 21:04:55 UTC
From: Jay in the Mojave <jay123a@qnet.com>
Message-ID: <3AA6A277.533897FA@qnet.com>
Source record: 169060

Hello John: I have built a few 20, 15, and 11/10 meter beams.

I like the use of the square aluminum tubing, around 1 1/2 to 2 inches in diameter, using thin walled 1/16 inch wall thickness, or if your bent on bullet proof, you can use the 1/8 inch wall thickness.

With the square tubing, boom to mast reinforcement plates, are a snap to make. The elements can go thru smaller square tubing, in the middle. Such as 3/4 inch round aluminum tubing, going thru 1 inch square tubing (about 12 " long), with a 1/8 inch wall thickness, this is bullet proof construction. With the 3/4" tubing 48 inches long and centered in the 1" square tubing, attached to the mast with a square U-bolt made from all thread (1/4" or 5/16"), hugging the mast, and going thru the 1" and 3/4" tubing, and being secured with lock washers and nuts, out be pretty good construction. The remaining parts of the elements can be made from 5/8" (36 inches long, with 3 inches inside the 3/4" tubing) and 1/2 inch round aluminum tubing, cut to 72 inches long will allow for almost 12 to 10 meter operation. With a wall thickness of .058 inches. Aluminum tubing material 6063-T8 is found all over, and is good stuff.

Use good marine grade stainless steel hose clamps.

Jay in the Mojave

4379. G5RV Dipole -- Works?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-07 21:12:50 UTC
From: Alan Watts <awatts@neo.rr.com>
Message-ID: <mvxp6.12697$a7.131492@typhoon.neo.rr.com>
Source record: 169050

Anybody have experience with one? How does a G5RV compare to, say, a 40M dipole on 40M -- at the same height? -- a 10M dipole on 10M?

Also, I'll have to run it through the near tops of some trees -- should I replace the bare copper horizontal wire part with insulated wire to keep from maybe starting a fire.

It's 102 feet long, and I can't run it completely free of tree limbs and foliage.

Alan

Jason,
A common way to mount a capacitive hat is between the
top of the coil and the whip. "Works fine... lasts a long
time". Another method is to use any support 'guys' as a
'cap-hat'. For example, using nylon cord as the 'guy',
just run a wire from the top of the coil down the cord
for whatever length you need. That assumes that your guyed
at the top of the coil...

Whatever works, works. I worked 39 states and both coasts from Texas, mobile on 160 meters during a 160 meter contest some years back. The antenna was a Radio Shack fiberglass CB whip loaded with a hand wound -- with # 24 wire! -- 4 inch by about 14 inch PVC base loading coil. Beat it? Sure, a lot of things would beat that. But whatever works.... works!

I used an ICOM AH3 tuner and tried tuning mobile antennas on bands where they were not resonant. A Hustler 80 meter antenna presented too much impedance at the coil to work well on 40 (and the base insulator caught fire). The 4 feet of mast below the coil worked -- sort of -- on 10 through 20. I went to a longer mast with better luck, but really, it wasn't worth carrying 11 feet of antenna just to use six feet of it.

Hi Charles,

Resonance has nothing to do with lobe patterns except as a function of physical length vs. electrical length. What you describe (having more lobes than the standard figure 8) is simply a physically big antenna used at a correspondingly short wavelength. The smallest doublet (very small in relation to a long electrical length) will still give you a figure 8 - matched or otherwise. Neither instance is resonant and yet both are possible without regard for resonance. Thus, there is no direct correlation between resonance and lobe pattern outside of the lengths involved. (Or, in other words, to describe an antenna as resonant necessarily fulfills the length requirements by inference; but does not constitute a separate criteria for describing the lobe pattern.)

As for performance being judged by the criteria of resonance. This is only true insofar as the losses incurred through neglect of SWR. You can lose power as easily through neglect at resonance too. Neither of these conditions is part and parcel to resonance, but rather more attributable to the human factor, not design.

It kinda depends on what you consider "certifiable". A number of measurements have been made of the Egyptian installations, and these are often used as proof of claimed performance. But closer scrutiny has revealed poorly calibrated test equipment for some measurements and, as far as I can tell, no systematic system of measurements at various distances and directions. Other criticisms are that the transmitter buildings are metal-sheathed and are likely radiating more than the antenna. Finally, some of the fantastic claims seem to be based on ground conductivity which might be much lower than its actual value. Some measurements were made in Egypt by a respected and independent engineer which seem to show performance greater than one would think from such a small antenna, although it was less than claimed. I don't believe a full set of measurements were made, however, and don't believe any independent determination of ground conductivity was done. As I understand it, the Isle of Man or one of the other new installations was supposed to be professionally measured, putting all doubts to rest. But these professional measurements seem to always be just a little out of reach for some reason.

It's well known that the field strengh from a broadcast station varies quite a bit in different directions and distances for a variety of reasons. That's why the FCC proof of performance requires quite a number of measurements in different directions and distances. I'm not aware of any proof-like set of measurements being made on any CFA installation, although some have been in operation for over 10 years now. Several good sets of these measurements by an independent engineering firm at a few sites would be a sure-file sales tool for the CFA, so I can see only one reason they don't seem to exist. All we seem to have is spot measurements here and there.

I have to state I'm not a real expert on the CFA. I've kept somewhat aware of the developements, but to nowhere near the extent Jack Belrose and some others have. So there may well be measurements I'm not aware of. It does seem, though, that really solid evidence of consistent performance comparable with a much larger antenna continues to be lacking, despite the years the developers have had to produce it. Some people might wonder why, but I don't.

The cone radials are usually a 1/4 wave at the lowest freq and the top hat is usually
a 1/4 wave at the highest freq. They are designed to cover a decade of frequencies,
example 50-500 mhz. I would suspect that you could get by with only 3 or 4 of the
radials before you would see any difference in rx.

This is just an educated guess, don't quote me on this. I have seen discones with 3 radials
each.

Hi Alan,

Even at its worst, it will still perform more than adequately compared
to a dipole.

As Charles notes, for the shorter wavelength (40M), you will observe
different lobes (this is not a condition relating to resonance) and
here you may suffer in comparison to a simple dipole for 40M - IF your
old contact happens to fall into one of the new nulls of the G5RV.
Instead of the figure 8, you can expect a cloverleaf with the new
nulls falling on the broadside axis and the old nulls still oriented
along the axis of the wire.

Now, IF your G5RV does exhibit deep nulls, then you can rightfully
expect it is working very well indeed! (Otherwise the nulls would be
filled by other radiating portions of your system such as the
feedline.) IF you should be so lucky, then simply turn the rotator
;-)

IF, on the other hand, your system is located low to the ground or its
balance is upset, it is unlikely to exhibit these nulls very strongly
(and the simple 40M dipole would suffer in the same way). In this
sense, either will perform equivalently (within an S-Unit).

Go ahead and choose insulated wire. However, this is not an absolute
guarantee against accident or fire. On the other hand, I have used
wire in direct contact with trees for years (insulated, yes) and never

observed any smoke (but it does rain a lot here - or it used to). The trees have done more damage to my longwire rather than t'other way 'round.

Thanks to all that replied to my TVI problem message. I now have a jumping off point in fixing all of this. One more thing though. People have mentioned common mode chokes and the ARRL Hints and Kinks book talks about them as well. Where is a good place to get the ferrite cores to wrap coax and other cables with? I am thinking about getting some of the snap on ones that AES sells for the smaller audio and power leads going to the effected equipment but those seem way to small for coax and larger power cables like the ones you might find on equipment with three prong grounded plugs. Any ideas? Thanks again!!!!

I don't get the multi-lobed nonsense. His primary band is stated as 40M and a G5RV is NOT multi-lobed on 40M. I once did the calculation, and my dim memory is that it takes about a 150ft+ doublet on 40M to develop secondary lobes.

G5RV is a great antenna on 40M, especially if you can get it up 40-50ft or so.

Ciao,
Barry N1EU

Mount it on an upside-down waste paper basket. Use big washers, if needed, to
strenghen the mounting area. (Hell, guy the damn thing, if needed.)

Then run a counterpoise wire through your apartment for the ground side of the
system.

That oughtta do it, for fixed station use.

And if you read it, you will see that it has NOTHING to do with the hoax that was posted here which was about "A Virtual Card for You" and "An Internet Flower For You".

So when you get unmixed up, you will see that Tony was right and you were confused.

"He`s the guy who put up 300 foot towers so that he could have his dipole "UP" in the clear, without any question whatever about it. And guess what - his verticals beat the socks off all his high dipoles."

Well, maybe Tom, W8JI, didn`t rip out his ground radials under his new horizontal antennas, and the installation simulated that over sea water or salt marsh. Bad for low-angle dipole radiation, but good for higher-angle radiation to reach closer targets.

Just pure speculation. I have no idea what Tom`s antenna farm looks like.

That depends upon your definition of "outperform". The G5RV's
matching section (series section transformer) gives a pretty good
match for coax on 40m and the fact that the G5RV is 0.78WL on
40m gives it some gain over a 0.5WL dipole.

My non-resonant 40m EDZ outperforms a resonant 1/2WL dipole by
the predicted amount.

It's hard to tell the performance of a G5RV from a dipole on
40m. It has slightly more gain and slightly less beamwidth.
Unless you trim it specifically for 40m, you will need an
antenna tuner.

The length of the wires for the cone is usually 1/4 wavelength and the
disc at the top is about .7 of that 1/4 wavelenght in diameter. The
book design calls for the rods that make up the cone to be about .02
wavelength apart or less at the bottom for
best operation. That is not to say that you can not get by with less.

Un huh. Maybe you should learn to read about the real aftermath, like
what actually happened after the Homestead hurricane.We all know how
it's supposed to work, and does when the scope of the problem is small
enough that it doesn't overwhelm the locals. That usually doesn't take
too large an incident.
Clearly your theories depart from the realities of life by a bunch.
Maybe someone who experienced the Homestead hurricane can set you
straight. I doubt it.

I believe that the "NakedWife" virus that you refer to might well be
real, but I was referring to the "VirtualCard" one that he referenced.
I thought my message was pretty clear - maybe not. Notice what I had
in parenthesis.

But I agree totally with your moral. I even carry it a bit further, I
don't open *any* attachments without careful steps, and running a
virus protection program. And I still got hit once.

Dick Carroll wrote:
"Maybe someone who experienced the Homestead hurricane can set you straight."

Dick Carroll has already told us there were people who sat and waited for a week to hear from any relief person so he must at least have hearsay information of developments following Andrew.

If there was something amateur radio could have done to alleviate the suffering of the people of Homestead, Florida caused by Hurricane Andrew, did amateur do it all? If not, why not?

Did Amateur radio win state and national commendation for meritorious service in the aftermath of Hurricane Andrew?

If so, this recognition should be saved in a perpetual hero file carefully kept and used to promote amateur radio. Is ARRL keeping a hero file? Yes, they have information from all back issues of QST. That is not the same as cultivating a hero file.

>Anybody have experience with one?

According to my experience, it's a surprisingly good antenna on 40m.
Yesterday worked BQ9P on 40m CW, and a couple of days earlier T32RD on the
same band, both in pile-ups and with 100W. The antenna is 50 ft up.

G5RV is a bit longer that lambda/2 dipole on 40m, which gives it some
additional gain over the dipole. The difference is not much though, but
gives at least some mental support. Those stations just happened to be in
the right direction.

I suggest you'll build one, I don't believe that you would be dissapointed.

> . . .

It's well known that although pure water has low DC conductivity, its RF loss is significant due to energy expended as its molecular dipoles try to orient to the alternating field. _Reference Data For Radio Engineers_ shows distilled water to have a dissipation factor of 0.04 at 1 MHz. This is more than twice the loss of PVC plastic, and more than 200 times as lossy as a truly low loss material like polyethylene. So I don't think "low-loss" is an accurate characterization of water. Rain water falling on a dusty surface, or for that matter through dusty or polluted air, will be more conductive in addition. The combination of high dielectric constant and fairly high loss makes water something you don't want too close to your loading inductors or anywhere there's a high electric field, such as between feedline conductors.

I've made measurements on 300 ohm twinlead that shows very greatly increased loss when wet -- certainly not what you'd see if water were a "low-loss" material.

If there's nothing else available try timber. Staple the antenna elements to it. Easy to readjust element spacing. Doesn't matter whether its wet or dry. No current flows in it. For durability soak in timber preservative before erection.

Measurements not needed. Basic prediction methods indicate
performance in the same ball park as a magloop of the same overall
dimensions. Considering the lifetime cost of ownership, if a small
cheap antenna, needed for only a few years, is good enough for a
broadcaster then by all means he should have one. Whether Clerk
Maxwell would approve is of no consequence whatsoever.

The G5RV is no better or worse than any other random length dipole
fed with random length high Zo twin feeder.

The predicted radiation patterns, taking all bands into account,
for practical purposes are omnidirectional - just like any other
random length dipole fed with a random length feeder. Just
superimpose patterns of all bands on top of each other.

And when erected in the average ham's back yard the actual
radiation patterns, in both vertical and horizontal planes, above a
vast range of ground conditions, don't bear much resemblance to
computer generated predictions in any case.

And if you incorporate a long length of coax in the system to
improve performance, you are fooling yourself.

To compare one dipole with another, one feedline with another,
download program VARNEY from website below. Takes only a few
seconds. Not zipped-up. Run immediately.

Then erect a random wire, roughly centre-fed, which fits
comfortably in your backyard. Tape measure not needed.

By the way - whatever you adopt - for all bands you will need a
tuner. Or follow Cecil's method of tuning by switching feeder
lengths. Program VARNEY allows feeder lengths and Zo to be varied
to find optimum lengths for each band. If you don't want to mess
about with feeder lengths the program will predict L and C
component values for a matching L-network.

I ran this thru elnec to see the difference. I see very little difference between a 160m dipole at 300 ft with poor ground and no radials, and the same dipole with VG ground cdx and 120 radials. Both cases I plotted the dipole at 300 feet high. Just for kicks I also plotted two 1/4 wl verticals over average ground. One with 60 radials, and one with 120 radials. With modeling, I see no real advantage to using a vertical. You will see that the angle at which you show 1 dbi is about the same with either the dipole, or the vertical with 120 radials. But at the higher angles you will see much more gain with the dipole. In the 8 dbi range with the dipole at appx 25 degrees compared to the almost 3.5 dbi gain at appx 19 degrees with the vertical with 120 radials. So looking at that, you would think the dipole would be about the same to far off dx if using angles below say 10 degrees. But going from most peopls reports in the real world, the vertical is almost always better. This is why I say the pattern and polarization itself must be a factor rather than the gain itself. I know this is a self conflicting statement, but it seems to be the case to me. And this is why I say be leery of using modeling alone to try to decide which is better. If you did, you might never try a vertical. Myself, I believe vertical polarization is superior to horizontal for long haul dx on the low bands at least, the gain of the antennas being equal. I know that in the commercial world they prefer horizontal, but I think the reason for that is it's easier to build a high gain antenna that way, than a massive array of verticals. Can you imagine the number of phased verticals it would take to equal a rhombic? Might not even be possible with the diminished returns on doubling the amount of radiators again and again. Much easier to just buy a half zillion acres and plant

rhombics or whatever in every needed direction.
But I'm not so sure there is an advantage to horizontal. I kind of think otherwise. I think if you could build an array of verticals that equaled the horizontal antenna, the verticals would win to far off low band dx. Toms setup pretty much proves this I think. Or to me anyway. His dipole is over a 1/2 wave up, has bukoo gain at certain angles, and is losing to a vertical that in theory should be inferior. I can't think of any other way to explain it other than there is a definite advantage to a vertically polarized wave on the low bands for long haul. Either that or the modeling is flawed in this aspect. I noticed when I was running both on 40m, the propogation would sorta tumble back and forth. But the peaks on the vertical antenna were always stronger on anything over about 1000 miles. Always 2 s units stronger to the west coast. And my the reports back to me were always reciprocal. MK

To see the plots made using elnec demo: These are shrunk down jpgs for faster loading..

> resonate to perform well. It seems that myth will be with us for ever.

On top of that, Danny, a frequency sweep of a G5RV will prove that
it *is* resonant on or near 40m. EZNEC sez, using the transmission
line feature to model the series section transformer, that a 102 ft
dipole with 30ft of 300 ohm ladder-line as the "matching section",
is resonant on 7.3MHz with a 50 ohm SWR of less than 2:1.

In fact, if one wants to optimize a 102ft G5RV for 40m, one should
make the "matching section" 31 ft long using 300 ohm ladder-line.
That will resonate the 102ft G5RV in the middle of the 40m band.

With a 102ft G5RV, using a 37ft 450 ohm ladder-line "matching section",
will result in a resonant antenna system with a 50ohm SWR very close
to perfect on 40m. All this information is easy to come by with
EZNEC using the transmission lines feature. EZNEC information available
at www.eznec.com

Well, it's a little better than random, Reg. 1/2WL of "matching section" on 20m is 1/4WL on 40m and 1/8WL on 80m. 1/4WL on 40m brings the system to near-resonance on 7.3MHz. 1/8WL on 80m brings the system to resonance on about 3.6MHz. The coax losses due to SWR on 80m, 40m, and 20m are pretty low. I know because, years ago, I set out to prove that the G5RV was a dog. I wound up proving it is a pretty good antenna for 80m, 40m, and 20m with 12m thrown in. As with any antenna, one needs to recognize the limitations. The G5RV *is* a dog on 30m.

Helical resistance film = coil = inductor with resistance = no surprise. I
always make sure that I use "non-inductive" resistors. One type uses a hair
pin of resistance wire wound on a form. Others are a flat film, no spirals,
like the tab types manufactured by Caddock. http://www.caddock.com/

> Presumably this is why they generate noise up into VHF/UHF

This is maybe due to the reverse recovery effect when the diode "snaps" off.
The results would be similar to what happens with a step recovery diode.

We use a lot of those on AC relay coils. The relays are the "typical"
industrial control panel mount type.

Mark, NM5K wrote:
"But I`m not so sure there is an advantage to horizontal."

If there weren`t, their commercial use would not be almost universal.

There is a basic reason horizontal antennas don`t work well for long-distance propagation over sea water. Griffith explains effects of "ground" very well in "Radio-Electronic Transmission Fundamentals" as follows:

"Let us imagine that we have a horizontal dipole which is 1/2-wave long, such as the antenna at first resonance in Fig. 41-3. The complete radiation pattern of this antenna is doughnut-shaped, as we find by rotating the cross-sectional pattern from the figure about the axis of the dipole. Now let`s position the dipole at a distance of 1/4 wavelength above the earth, assuming for the moment that the earth forms a perfectly conducting surface. The portion of the energy which travels straight down to the earth is reflected straight up again, undergoing a reversal in phase of 180 degrees at the point of reflection, just as is true of an incident signal encountering a short-circuited end of a transmission line (Chap. 25). This energy arrives back in the vicinity of the dipole after traversing 180 electrical degrees of distance and being shifted another 180 degrees at reflection, so that it is in phase with the new energy leaving the antenna on its journey upward. The signal leaving the antenna and traveling directly upward is thus reinforced by the reflected signal, having twice the field intensity in this direction as would be produced by the free-space dipole carrying tjhe same current.

If we consider a point which is far away in the horizontal direction at right angles to the dipole, we can see that the direct signal and the ground-reflected signal will have traveled the same distance to the point; the reflected signal though, will have been reversed in phase at reflection, so that the two signals will be 180 degrees apart in phase opon arrival at the point and will therefore cancel each other. This condition holds true in all horizontal directions---."

From the above, you can see the problem with getting low-angle radiation from a horizontal dipole when the earth supplies a strong reflection. Solutions are sorry soil and really high horizontal wires. If you have a dandy radial system over sorry soil, you might get better dx from a dipole by ripping out the radials.

I laugh when I read a poster tell us how self-resonant dipoles are somehow superior to other dipoles. A 1.25 wavelength dipole is certainly not resonant, but gives superior performance broadside. Ever heard of the 5/8 wave vertical on VHF? Wonder why it is used? think about it.

If there is are any doubts about the accuracy of Cecil's comments below, the doubter should download the demo version of Roy's Windows EZNEC and then download the design file for Cecil's 130 foot LL fed dipole. Then by changing the length of the dipole and LL sections in EZNEC and running the frequency sweep feature of EZNEC he can easily see just where the antenna _system_ will be Resonant. He can then also observe the patterns to see what directionality the antenna will have on any frequency of interest. Change the antenna/feed lengths to that of Varney's original G5RV antenna and see exactly what it does.

Resonance in an antenna _system_ is what we are generally after. That antenna _system_ includes lots of circuit elements, not just the dipole itself. With the G5RV, or Cecil's derivation, the length of the LL feed is a critical element.

I used to have 5 separate conventional half-wave dipoles in my big back yard. I recently took them all down and replaced them with non-resonant dipoles using Cecil's design principles after doing the study I described above. Works for me.

Those wishing for a more conventional looking "top hat" should
consider loading a bicycle or two up there on the roof.

Where I live, people drive around all the time with bicycles mounted
up there. No reason why you couldn't do it permanently.

No whip required, and the bike racks are available at your nearest
bike shop. Stealth mobile.

If you have no other way to make a standing-wave antenna electrically resonant, you will improve its performance by physically adjusting its length to resonance. This is no myth! Any uncompensated reactance in the antenna circuit will impede current into the antenna and reduce its radiation.

I have used the L-tuner and T-tuner. Seems to me the main disadvantage of the L tuner is that it does not act as a tuned circuit and will radiate harmonics. The T-tuner seems to function as a band pass filter. Just my observation. The main difference could be the type of feed. I use the MFJ-989C with window line to feed a doublet. I use the L-tuner (homebrew) to end feed a wire. The "false resonance seems to be a mecahnical short to disable some of the turns on the variable inductor, when using smaller inductances.

Hi Cecil,

Your statement underlines my point, you had to appeal to length to
obtain a change in pattern.

Resonance can be forced with lumped components such that a very small
physical antenna can be made to appear to be large electrically.
Contrariwise, a physically very large trapped antenna can appear to be
small electrically. Both can be described as being resonant.
However, resonance in and of itself has nothing to do with radiation
pattern.

Hi Leland,

When I designed telephone equipment, I learned a lot about inductive kick from the K1 relay the home phone connects to at the central office. For a short loop, this kick ran at something like 1 to 2 KV and you did not want to snub it too heavily. The reason why is that by snubbing (or even a perfect short) you keep the relay latched longer when you are actually trying to break the connection (and unlatch the relay). In fact, the relays that operate during dialing (boy that is ancient technology) are held latched by design even when the current is broken.

Then I got around to design for Steppers that I had to supply at 10 times their rated voltage to "quicken" their response.

"But I`m not so sure there is an advantage to horizontal."

Suppose 10 degrees is good for F2 propagation to a distant station you want to work. See Fig 23 in the new ARRL Antenna Book on page 23-24.

The angle a ray from your horizontal dipole makes with the earth is also 10 degrees to produce the desired reflection. That places the reflection point far from the dipole. That reflection point is the launch site for the out-of-phase debilitating signal. That is where you want a poor response. I already said, Tom`s radials are located I know not where.

Hi

I have been using a cobweb for about 3 months now and find it works well
for it's size.
on 10 mtrs I prefer my 1/2 wave cb antenna as it has a higher bandwidth.
My cobweb is about 3 feet above my roof and I have worked vk several times
which is good from my qth.

A good buy if like me you are limited for space.

They are an old device manufactured by Metropolitam Vickers, (GE will probably have them probably called transient suppressors), very popular on Radar set sduring and just after WWII. the last samples that I had from the manufacturers was in about 1975/6. Somewhere amongst my junk I have the spec sheets for the range. By today's component standards a bit Heath Robinson, but I see no reason why the material could not be mounted in a modern mount and used where high Voltage peaks at some power need to be controlled.

> > Diodes alone do not completely stop the ringing, some form of resistance
> to

> purpose.

Sometimes the forward resistance of a diode is too low and it sustains ringing for longer than better methods where a proper disipative resistanace of the correct value is engineered into whatever it is that you wish to supress. LR should be such that all of the energy is disipated before the second overswing, in other words critically damped instead of leaving it to pot luck that the diode forward resistance will do the job. Also if the excess energy exceeds the disipation capacity of the diode then you will blow a lot of diodes and either burn out a lot of points or blow up a lot of control transistors.
Of course the hardest thing to damp and control is a DC motor wher the stored mechanical energy and Lenz's Law produce a back EMF of the same polarity as the original supplied voltage, here a single diode does little good and a more complex arrangement is required. Where Hams might encounter this problem is with rotators

I suppose you never saw a solid carbon resistor filed to adjust it's value,
this was often done for meter multipliers and shunts when accurate
caliobration was required, Hams that built their own multimeters with
surplus moving coil meters became quite familiar and expert at this
practice. In those days being a good engineer was not sufficient you always
needed to have a few bodges up your sleeve. I got so good at it my friends
said that I would make the ideal prisoner of war :)

4444. AH-4, stainless whip and 6 meters

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-08 20:16:18 UTC
From: Rudy Marcelletti <rudym@net-link.net>
Message-ID: <3aa8f50c$0$1630$bbae4d71@news.net-link.net>
Source record: 168943

My Icom AH-4 coupler, spring and whip, works pretty well (considering what it is) on all bands from 7 to 30 MHz, however, 6 meter performance is down with the long whip. The rig cuts back in power to about half, if the IC-706MKII meter is accurate at all, and the meter swr says under 1.5:1 or so, once in awhile, 1.7:1 and every now and then I will get almost 90% output.
According to Icom AH-4 coupler instructions, half wave antenna lengths and multiples should be avoided. Well, 6" spring and 102" whip is a half wave on 6 meters (52.000). So I added a foot to the base of the whip above the spring (total length now 124" well actually about 130 inches if you count the feed wire from the coupler to base of spring). Coupler now is matching a bit better, especially down where I want it (50.125), but still less than 75% output according to rig meter, and I do whack more overhead stuff. I have not put a "real" meter in line to see what the actual results are, but anyone have any ideas. System works great for what it is on HF and tunes a Hustler 75 coil on a short mast just fine. Other than swapping in a 54" whip (coupler loves it!) is there any point in trying anything else with this antenna/coupler setup? What about putting a small disc between the 12" bottom mast and 102" top whip, sort of a little cap hat? What about a small disc on the whip itself, say about 4 or 5 feet above the vehicle? It would still be fairly safe from hits here. Top hat is out of question where live, unless, I could make it out of springs or the like.

Hi Gary,

Perhaps by another name? Strowger perhaps (the stepping relay used to
translate the pulses of a dial based telephone into a cross-point
matrix)? This was invented by a moritician who found the live
telephone operator was directing his business to another mortician!

4450. Re: TenTec two-element antenna tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-08 23:14:09 UTC
From: "Peter O. Brackett" <ab4bc@ix.netcom.com>
Message-ID: <9893iluae1@slb6.atl.mindspring.net>
Source record: 168923

Thread:

Hey, the T-tuner is basically a 3-element high pass filter [C1-L-C2] with two capacitors in the "hot" side and a single inductor to ground. Any filter with adjustable elements can be used as an impedance matcher. The Pi-Tuner is actually a low pass filter [C1-L-C2] with two grounded C's and a floating L, and can effect impedance matching with the added benefit of harmonic suppression because of the low pass filtering effect.

Not much harmonic supression in T-tuner, since it is a high pass filter, and don't expect it.

A properly configured L-tuner [L-C] can do as good a job at harmonic suppression.

Of course, your transmitter should have it's harmonics suppressed far enough to begin with. So don't depend upon the "tuner" for harmonic supression.

The "tuner", whether T-Tuner, L-tuner, Pi-Tuner, or whatever, should be thought of simply as an adjustable impedance transformer. The T and Pi tuners have three independent adjustments, more adjustable variables than are necessary to match any given impedance ratio, and so....

With three independent adjustments, the T-tuner and Pi-Tuner can have numerous different "settings" of the controls to effect the desired impedance transformation. Usually only one of those several settings is the lowest loss setting. Beginners may have problems deteriming which of the various settings that result in 1:1 VSWR are the lowest loss. A good rule of thumb is that since the inductor is the lossiest element in the tuner, the setting that utilizes the smallest value of inductance is the lowest loss setting.

With only two independent adjustments, the L-Tuner will have only one "setting" that effects the desired impedance transformation and results in a 1:1 VSWR. You simply have to settle for whatever "loss" results from that one setting.

Depending upon conditions, that setting of the L-tuner may result in less or more loss than a corresponding T-tuner or Pi-Tuner.

Widespread practice and usage indicate that the "T-tuner" is the most versatile in terms of the impedance matching range for a given size of capacitors and inductors.

Yes a better ground plane (more radials or longer radials if you've got too short ones) will reduce the resistive losses of a ground plane antenna, which without any other tuning will lower it's impedance down into the 30 to 40 ohm range, which will give you a worse SWR than a lossy antenna that has a 50 ohm impedance. The SWR bandwidth will also be narrower. The efficiency will be higher and you'll get out better. If it's a 5/8 wave vertical you need some kind of matching arrangement at the base anyway. Retune it and/or use another antenna tuner. If you t a real good SWR across all bands without the hassle of tuning is the most important thing to you then a 50 ohm noninductive resistor will work great. If you'd rather radiate some signal you'll have to put up with the inconveinience of matching the impedance of an efficient antenna.

Unshorted turns are much worse, because the Q of the self-resonant circuit formed by the unshorted turns and their self capacitance is high, large voltages are formed in these turns, and so-called "suckouts" are formed. In the shorted turn coil a small amount of power is lost in the shorting connection, but that is a lot better than letting the unused turns "float". Also, the coupling to the shorted turns is small.

The unused turns should always be shorted. I have had some bad experiences with unshorted-turn coils that went away when the short was reinstated. The trouble was that at certain frequencies, as I approached the desired inductance value, the tuning would suddenly go berserk and it was impossible to get tuned because of the interactions.

The shorted coil may become series self-resonant, but at a much higher frequency than the unshorted coil, where it usually causes no problem.

dead lucky, you might say.

No, you might know them by the generic name "Polar Relay".

Look in the RSGB Communications Handbook
10.5 The Polar Relay and Selector Magnets.
There is a diagram (10.8) of the mechanical and magnetic operation of this
type of relay and the wiring (10.9) for various modes of application.

"Polarized relays such as the Carpenter type are often encountered in
telegraph practice. Like the double-current magnet they are completely
balanced mechanically and side-stable. When current is removed entirely from
the coils, the contact remains switched according to the direction of the
current prior to removal. There is only one change over contact, the fixed
contacts being designated mark and space, and the moving contact as the
tongue. Generally there are two identical coils."

You might use the Carpenter Relay at the end of a long telegraph line where
the voltage and current to drive a teleprinter may be attenuated and a local
voltage and current source may be used to drive the TTY or you might use the
Carpenter relay to translate Double-Current signalling to 2-wire antiphase
signalling, or to Single-Current or vice versa etc.
Or to run several TTY off of a single line etc.

Relay logic "can" be fun :)

> me.

A preamp in front of a mixer on 160 m will do nothing for you.
In fact it will restrict your dynamic range and make the situation a good deal worse.
The noise figure of a mixer is 10 dB
this amounts to 2,500°K noise temperature.
The sky noise on 160 m at the best time of day is 9,000,000°K
changing the noise from 9,000,000 to 9,002,500 is only worth 0.0012 dB you would not be able to measure such a change.
Adding a 20 dB pre amplifier in front of the mixer will reduce the mixer noise contribution to 25°K (assuming that a low noise figure transistor is used for the input transistor to the amplifier and it is nearly an ideal amplifier.
However the Sky noise will now appear to be 100 x 9,000,000 = 900,000,000°K
This will overload the output transistors of you receiver and the AGC will shut down the IF gain by at least 20 dB.
So now you have lost dynamic range and also the ability of the AGC of the receiver to cope with the QSB and fading of the wanted signal.

The only way to get more S/N is an improved antenna or for the transmitter
power at the other end to be increased.

This is the one area where the linear transmitter amplifier does come into its own.
If you require further information I will rehearse the calculations for you.

That can be a problem also - thousands of volts on the floating end.
Why can't tuners take a lesson from screwdriver antennas and use
finger stock with a shorting sleeve?

Somebody, a couple of years ago, said a good rule of thumb is to make
the radials the same length as the vertical element.

> than the unshorted coil, where it usually causes no problem.

This is from my Hints and Kinks Dept: I run a fairly large Texas Bugcatcher (tm) and find myself plagued with self-resonances in the unused (shorted) part of the coil on 20, 17 and 15 meters. This problem goes away if I leave the jumpers for the lower-frequency taps, those for 75 and 40 meters, in place along with the normal one for the higher bands. I suppose the ideal situation would be to short out every unused turn on the inductor, but multiple shorting taps seems to work fairly well also.

I forget who it was, but somebody made a good sounding argument that
the higher the current maximum point is on the vertical, the longer
the radials need to be.

Mogens wrote:
"Would the right answer be 1/4 wavelength? But a good groundplane may detune the swr of the antenna."

That is about what one "expert", B. Whitfield Griffith, Jr., says. He says the vertical rod with its radials resonates much as a 1/2-wave dipoles does. The "dipole" can be off-center fed. That is the vertical rod can grow while the radials shrink, keeping the total length of rod and radials at near 1/2-wavelength. When 1/2-wavelength is reached, no radials at all are necessary for resonance.

Griffith says that another way is superior. He says the ground plane can be made very extensive as the surface of an automobile, plane or ship. If this is done, he says you can expect as much as 3 db gain over the usual groundplane antenna.

4473. ft100d and atas 100 problem...

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-09 16:24:35 UTC
From: jeff wright <wright00@att.net>
Message-ID: <3AA90382.20AA8493@att.net>
Source record: 168945

i am having a problem with a new ft100d and the atas 100.

on 10 meters, i hit the tune button, and the antenna moves and the radio

shows the tune icon and the 'o' symbol. as soon as i key up, the high
swr symbol appears with the 'x'. what is going on?

i can move the antenna all the way up or down manually and tune using
the tune button. the receive audio comes up like it would for a tuned
antenna and the icon shows tuned ('o'), but as soon as i try to use the
mic, i get the high swr icon on 10 meters.

antenna tunes great on other bands.

i am using another antenna for 2/440 and have the radio set up that way.

your thoughts?

Tom, DL7JSK asked about lengthening his groundplane radials for improved performance on 10 meters. I responded that some large surface like a car body would be better.

That is a faux pas for 10 meters because a car body is small at 10 meters. Sorry, I was thinking UKW.

Gary, your analysis is reasonable if antenna sensitivity is a
normal sort of value. But the antenna in question is is an untuned
ferrite rod of great insensitivity. Any gain between it and the
noisy first mixer would be very welcome.

A better solution on 160m would be to tune the winding and match it
to the receiver input impedance via a link coupling.

Gary Peach wrote:
"A preamp in front of a mixer on 160 m will do nothing for you."

Agreed. That is the usual case because the troublesome noise is external to the radio.

I didn`t endorse preamplification. I simply suggested searching for a "preselector" which often can help signal to noise ratio. Mike said he wanted selectivity. ("preferably filtered just for 160m").

Mike said he wanted 25 db gain and something about a submarine antenna. I assumed he had his reasons.

Hi Gary,

I have worked with variants of your Carpenter Relay. They were small units from Arrowmat (sp?) and we investigated their use in home telephone equipment. We were concerned about the limitations enforced by Ma Bell (and the FCC) at the time with these "latching" relays. Those limits were the current necessary to trip the state and the holding current to maintain the state. The two were different by something like 10:1 making them very appealing.

Depending on what distance you want to work, either don't worry about height
of a horizontal antenna and work locals (within a few hundred miles) using
high angle radiation (presently popular is the buzzword NVIS=Near Vertical
Incident Skywave) OR if you want to work DX use a vertical, then only one
support is needed and the support is the radiating element. A full quarter
wavelength vertical can easily be mechanically sound without guying as low
(in frequency) as fourty meters. You just have to have good foundation (in
the ground or part of a building) to mount it to, AND a good radial system
if you want it to be efficient.

Wes, I visited your easy to read website. I note your measurements to investigate difference in loss between wet and dry ladderline were made at 50 MHz. Presumably you had to go up to VHF to find differences great enough to measure reliably.

The formula you provide to translate the VHF data to lower frequencies I think is incorrect. Your formula (loss proportional to sqrt(F)) is applicable only when line loss is nearly all due to conductor resistance.

But the ADDITIONAL loss due to rainwater MUST be in the dielectric and dielectric loss increases directly proportional to frequency. So the extra dielectric loss due to rainwater on 450-ohm ladder line at, say, 2 MHz is 1/25 of the values you have reported at 50 MHz. It is less than the already-small conductor loss and would not be noticeable.

I think you said your measurements were worst case values obtained with a wetting agent added to the water. I wonder what the loss-factor of wetting agents are at 50 MHz.

With ladderline by far the greater proportion of the dielectric volume is air, with a small amount of plastic and very little water. I have sat in the shack with one eye on the Refl.coeff meter and the other looking out of the window watching great raindrops bounce off the ladder line. The only change observed on the meter has been synchronised with the antenna swinging in a gusty wind. But I understand rainfall can be heavier in the States.

Just as an update since others have brought this up, Dr. Cohen does not write articles for ham magazines anymore--after many from 1995-1998-- and declined to write one for QEX. Many others have written fractal antenna articles, including KF7BS's article in Octobet 1999, 73 Magazine.

The only valid fractal antenna source of info for hams on the internet is on www.n1ir.com, which will be up in coming weeks.

Incidentally Dr. Cohen has concerns about radio amateurs and others who are placing material in copyright violation on their web sites and in lieu of recent legal decisions on copyright violation on the web is pursuing legal efforts to stop such in 3 cases. The same concern for violation can and will extend to published articles.

Radio amateurs are also reminded that fractal antennas are protected by 3 US patents to date and covered in several other pending patents. Single use experimentation should not be interpreted as commercial permission under any circumstance.

This is a public notice and others are invited to transmit it elsewhere as appropriate.

73 to All,
Phil de N1ZKT

I agree with the harmonics when only looking at the tuner. I use the T
tuner with a balun and window line. That combination seems to keep the
actual radiation of harmonics lower than with the long wire. I am mainly
talking about TVI to a weak TV channel 3 while running SSB with power on 7170.
This is not my own TV but down the street. The L-tuner with the end
fed wire is much worse. This is probably because there is no feed-line
mismatch on the other frequencies using the end fed wire. I am using older
equipment but also use a high power low pass filter that starts cutting off
at 30 MHz (in fact has about 3db loss on 10M) after the linear.

Just bought the IC-706 MK2/G and AH-4 combo for portable- stealth condo use in FL. Figured I'd run out some wire and attach a ground clamp to a cold water pipe. Any other suggestions ? If I am on the right track are there any suggested wire lengths that you've had success with ? Appreciate any input from AH-4 users. Tnx, 73-Brian K3USC

I believe Mike lives in the British Isles. Not many mountains there.
That was one reason I suggested a web search. There are several sites on
this side of the Atlantic I could have suggested, but I thought he would
find one of those Dot co companies instead of a Dot com company that
might be easier for him to deal with.

Best regards, Richard Harrison, KB5WZI

Hi All,

For the humor impaired, this is fair notice that you may consider the
following material offensive (or worse, boring). And now to ape the
style above:

This is public notice that the above statements have been lengthily
responded to and answered in every manner that is in fact actionable.

Further, such notice as to patent coverage has been revealed to have
been fraudulent statements in the past and that no activities in this
forum have even come close to those claims that have been allowed by
the patent office.

There are also other correspondents who have submitted papers that now
show considerable refutation for the general and unsupported claims
made about fractal antennas from the source responded to above, and
their references. At least one of these papers is going to a real,
professional based publication that is neither a vanity rag nor an

exotic, academic broadside of self aggrandizement.

Hams should be aware there are many outlets to information about fractals and one such example are my several hundred pages of design and modeling data available at
http://www.qsl.net/kb7qhc/antenna/fractal/index.htm
and at
http://www.seanet.com/~rwclark/antenna/fractal/index.htm
The visitor to each site should note that although identical in appearance, there is some variation in material included.

I should further note that these pages contain designs that are considered "offensive" by the source responded to above simply because they reveal the entire scope of several seriously flawed logic touted in this forum. Their rejection of scientific enquiry was palpable and defensively responded to with threats of "possible legal action" which of course means nothing. All things are "possible." What is more to the matter is that nothing has been "done legally" (in spite of statements made above) and such claims leave open the "possible" prospect of claims abandoned through the passivity and inaction of the source responded to above. This is the more "probable" status. ;-)

End of fair notice - send on the fractalawyers! :-)

Richard, I've been wondering how to generate a fractal antenna without
any possible violation of fractal patents. Here's what I came up with:
Drive around until you find a two-color cat that has recently been run
over. You know, the kind that is dark on the top and white on the underside?

Skin the cat, flatten out the skin, and let it dry. Then take a #12
wire and bend the wire to match the pattern that separates the dark
part of the cat hair from the white part. Go round and round as many
times as necessary to get the dipole to resonate on the desired
frequency. The result is a perfectly unique fractal antenna without
possibility of a patentable mathematical description.

If I can find someone to hold my cat while I bend the wire, I'm going
to try it myself.

Hi Cecil,

Glad to see your offering in the spirit of humor....

Unfortunately, you "may be subject to legal action" given this "may be
covered by patents pending" referencing claim 3.b.2.ix. in an
abandoned fractal patent. (There seems to be a morose consistency in
what is sought and what is abandoned.)

Then again - you "may" not.

Hmmm, too bad you didn't submit this in the unregistered Lottery
offered here under the rubric of "Fractal Challenge." What would be
the FOM for this novel invention of yours? I wonder where the money
went for that one. I wonder if the state of Mass. is aware of this
violation of gaming laws. ;-)

Well, we can all sit back on our heels and wait to be described as the
Wakefield killer (no apologies heard in that debacle either). That
thread still has life, given recent entries, and certainly is one of
the more "successful" threads started by herr doktor and krew.

Ah, the light touch for a friday afternoon's pursuit. Thanx. :-)

Thhis is the sort of problem That I was trying to get some discussion going about some time back for 136 kHz and Antennae over very small dimensions compaired to a wavelength that would fit into a typical suburban garden.

> A better solution on 160m would be to tune the winding and match it
> to the receiver input impedance via a link coupling.

I think you are scratching around here at what the guys did in the 30s with reactance tuned TRFs and frame Aerials.

This would of course improve AE efficiency far more than providing a high gain amplifier to a very poor Antenna.

At the receiving site it is never possible to get better Signal to Noise than that in the free space immediately adjacent to the receiving AE.
Because Ts = Ta + Tr

In the adjacent space the Signal to Noise is
S/ kTaB
At the point of listening the Signal to noise is
S/k(Ta+Tr)B
The degradation is
(S/kTaB)/(S/k(Ta+Tr)B)
=Ta/(Ta +Tr)

In the case that you cite.
Ta = Tsky AE% + To(1-AE%)
where AE% is the Aerial efficiency.

I think that you are suggesting the AE% is of the order of 1% or less.

T Sky is 9,000,000 K
So we have
Ta = 9,000,000 x 0.01 + 300(1-0.01)
= 90,000 + 300
= 90,000

Putting this into the mixer would give a Ts of
90,000 +2,500 = 92,500
Compare this to the 90,000
10 log (90000/92500) = 0.12 dB difference in S/N

A 20 dB preamplifier will not improve on this Ts by more than the 0.12 dB
that we have in hand.
The Signal to noise ratio will not be enhanced.
We will be passing a lot more noise through the Rx thus reducing the dynamic
range of the Rx and raising all sorts of other problems.

Hardly worth the trouble unless you are using something like PSK8 with
Forward Error Correcting.

If that is the case then communication margins can be enhanced more and
cheaper digitally by using better encoding methods.

How bout a fractel mobile rig. I've been asked to "wind" this car. Would I be in violation? The only way I see to flatten this thing is at a junk yard. But if I do that, I may lose some of the special properties I see in this design. MK http://web.wt.net/~nm5k/fracar.jpg

> "preselector" which often can help signal to noise ratio. Mike said he
> wanted selectivity. ("preferably filtered just for 160m").

The passive preselector is a good idea.
At least three sections for a roll off of at least 18 dB / Octave

I was attempting to save his money, and anyone else that is reading this
thread caught up in the vane attempt to improve reception by adding more
gain.

Receiver gain should never be more than enough to amplifiy the front end
noise to the threshold of hearing or if a machine mode then the threshold of
the decoding equipment.

More gain only causes lots of other problems and reduces dynamic range.

Many of the problems with receiving on 160 m is because in most Ham cases
the receiver is designed for 28 MHz
A horse of quite a different colour.

> Mike said he wanted 25 db gain and something about a submarine antenna.
> I assumed he had his reasons.

I think that is the only difference between us;
I did not assume anything. :)

His submarine signals are a few octaves below 160 m, HI HI

Any commercial 2-way radio dealer should be able to get you a good quality
antenna.
Just tell them the frequency range and connector style.

The radio has SMA female connector on radio. Or
> do I have to make it? Should I just buy the $25 special at Radio Shack
and
> then try to cut (tune) it myself?

What frequency range is it designed for?

If you design a 1/4 wave antenna, it's approximate length will be 5.9 inches
from ground plane to tip.
if you use a 1/2 wave, you will need a special base, and also for a 5/8 wave
antenna. The longer the antenna, the more the gain (usually) matched
properly of course. You could also use a 5/8 over 5/8 or a 5/8 over 1/2 wave
phased aray for more gain. Look at some business vehicles and see what they
use.

And find a BNC to SMA female adapter?

Roy, the topic of conversation is Ladder Line. With flimsy 300-ohm junk, where the line provides a gutter for rainwater, anything can happen.

But out of curiosity, at what frequency on the 300-ohm line were your measurements made ?

On what length (feet or metres) of 300-ohm line were the measurements made ?

What was the total measured dBs of the 300-ohm line ?

What was the percentage increase between dry and soaked ?

And, of vital importance, what measurement method was used ?

Finally, what is the estimated uncertainty in the measurement of dB differences ?

Were you able to determine the change in line impedance and propagation velocity between wet and dry from your measurements ? This would have been of use in distinguishing dielectric loss from copper loss.

Source record: 168872

The other stud mount you refered to is probably the Larsen LM mount. The strength of the mount isn't quite as strong as the NMO because the top ring holding it down is plastic. Also, there is a square plate with 4 corners holding the LM onto the roof. They don't have as much surface area as the NMO mount does. The LM stud is not silver or gold anodized either, making it more susceptable to corrosion. There is usually a white powder on the connection when you unscrew it and look at the stud or in the antenna base. Another thing, i found where the coax solders to the under side of the LM mount breaks off easier.

I have seen both antennas preform over the last 10 yrs on the job, and both seem to get the same range and tune up the same. It is usually just personal prefrence.

I hope that I helped answer your question.

Drill the hole, it will work better.....

"Alan Watts" <awatts@neo.rr.com> wrote in message
news:mvxp6.12697$a7.131492@typhoon.neo.rr.com...
Anybody have experience with one? How does a G5RV compare
to, say, a
40M dipole on 40M -- at the same height? -- a 10M dipole on
10M?

Alan:

I used a G5RV for several years at home QTH . Center at 28
ft. and ends
at 18 feet. I used 450 ohm ladderline and had a section
added I could
switch in and out to get a good match on 40 and one of the
other bands
without a tuner. Other bands I used the MFJ 300W versa-tuner
on.

It did work, but I replaced the feedline with 450 ohm
ladderline all the
way to the tuner, and it made a tremendous difference in
effectiveness
with the antenna. I'm using a homemade 4:1 with the big
T-200 core
at the output of the tuner. I also tried W2DU suggestion of
balun at
input of tuner and made a homemade tuner with a roller
inductor,
but haven't experimented enough with it to tell any
improvement in
that regard.

I suggest you go with ladderline. I brought the ladderline
in by
splicing a short piece of good 300 ohm ribbon through the
window
frame.
If all you want to do is 20 meters, then go ahead and coax
it.
There is no good reason to use the coax if you can do it
with
balanced feeder. Besides, ladderline is cheaper than good
coax. Good Luck WM9D Mike in Kokomo IN

4502. Re: Radial length

Source record: 168874

It looks like the takeoff angles are close.

I was under the impression that a 1/4 wave antenna using 1/4 wave radials had a higher angle of radiation than the 1/2 or 5/8 wave using 1/4 wave radials. Probably just a few degrees. Take off angle of a 1/4 wave is about 35 degrees, the 1/2 wave at about 32 degrees, and the 5/8 wave at about 28 degrees. I also under stand the antenna height above ground affected the take off angle as well. I am refering to antennas with no droop in the radials. I wonder what your modeling program would find out about all three antennas using 1/4 wave radials and elevated to 1 wavelength above ground. Does the gain really change alot or is the vertical pattern (takeoff angle) just lower on the higher gain antennas.

To answer Tom's question, the factory 5/8 wave antennas that i used had 105 inch long ground plane radials.

Dr. Cohen confirms that Richard Clark is one of the individuals who will be served with a formal cease an desist notice for copyright violation on his web site . This is not "possible legal action". It is step one in the full legal proceedings as needed.

There can be no refutation of claims as there are none posed.No statements of Dr. Cohen lack validity. Mr. Clark is libeling Dr. Cohen.

Hope this helps. The rest happens, as they say 'off line'.

>differences great enough to measure reliably.

No. The Hewlett-Packard 8510C Vector Network Analyzer has a lower frequency limit of 45 MHz. I figured 50 MHz was a 'rounder' number. As I stated, the physical length of the line sample was limited to 12 feet because the equipment was located in a 16 x 20 foot shielded room.

My original intent was not to measure the difference between dry and wet line. The wet measurements were almost an afterthought. I stipulate that the wet data are less accurate than the dry data but I included them to support anecdotal reports of increased loss/changes in tuning when installed lines are operated while wet.
>
>The formula you provide to translate the VHF data to lower

Good point. However, I state in the text just above the formula, that the loss at other frequencies can be *estimated* by using the formula and that it does neglect the dielectric contribution.

I wish I knew. I tried a couple of things, primarily just a detergent, e.g. dishwashing soap. The measurements were made using my (former) employer's equipment on a non-interference, personal-time basis. I wish that I could have more thoroughly investigated this aspect of the problem but it just wasn't possible.

I ran some of the numbers by others who thought that they were plausible. In hindsight perhaps I should have left some of this out until I could do more work. But... I'm retired now and no longer have access to the equipment so that is out of the question, unless the stock market keeps going as it is and I go looking for a job :((

It would have been interesting to trap the water on the line by freezing it and not using a wetting agent, but I live in Arizona and that's a problem <g>.

Hi Richard,

The joke is old, old, old.

And it wasn't a joke when the temblor hit my office in the fill area
south of Seattle last week.

The first thing lost (literally) was telephone service (of all kinds).

Just think of the level of service if it had been "the big one."
Hint: it wouldn't have been any better. And this is for a region that
has been going through earthquake preparedness for 25 years and has a
local FEMA office. One of the Canadian stations noted that our
president had just cut funding for this preparation because "it wasn't
showing any payback." Compassionate conservatism - yeah, sure. My
heart bleeds for you, but I a'in't forkin' over a dime.

Hi Roy,

You are responding to one of those old wive's tales about the
non-conductivity of water. Yeah, in the laboratory (and still with
great effort, expense, and time).

Measure any rainfall and you are guaranteed to observe a pH other than
7.0 which means it contains free ions. And guess what, free ions make
wonderful charge transports and thus support current. Probably
another application of non-dissipative resistance. ;->

You can also make an all copper version of the ARX2B, the 3dB ringo. I've been using one, the same one since 1994... fed with 450 ohm ladder line, a 300 ohm Q-section and a half wave balun inside the shack to the 50 ohm line. Or you can use a coaxial balun at the antenna and run coax all the way down.

The only problem with end feeding a half wave antenna is the gross mismatch.
You'll nee some sort of L-C configuration to make it work into your feedline.
The Ringo is a half wave device... they use a tapped loop and the associated
capacitance to make it look like a tapped parallel tank for Z matching.
The half wave over a G.P. will show a somewhat lower radiation angle and some
(abt. 2dBd) gain. Or so the books say...

Probably one of the best places to look is the Polyphaser website. Their book is well documented and tested.
Antenna cables should enter the building at the same point as does the electric company's line... and should be bonded to ground there (The Entrance Window). The antenna should be bonded to the tower at the top and (in your case) where the cable leaves at the bottom of the mast (assuming that you're using a tripod roof mount). Running a separate ground wire from the mast?.. naw, the cable's shield will probably be sufficient (assuming RG8, 213, LMR 400, etc.)
As regards dealing with the center lead of the coax, Polyphaser's capacitivly coupled gas tube would be the best way to go, but I don't know what the lowest frequency you'll be using is and that may preclude using one of them. Probably best to use a coax switch with a grounding position and leave it there whenever you're not using the radio. Take note, many antennas boast that they are "DC grounded" which would seem to mean that they are also lightning grounded... NOT SO! Polyphaser goes through the motions to explain why and I've seen that phenomenon take out a customer's VHF Hi-band base rig's front end... no smoke of fried chassis, just lots'o deafness.
BTW, two ground rods are better... just make sure that you space them twice their length apart... it has to do with energy saturation of the earth... more Polyphaser stuff.
Oh, leaving the cable unconnected during a storm... put in a camera focussed on the floating end... the light show will be spectacular... just make sure to get the camera out before the roof burns through or you won't have any pictures. :-<

This is usually traced to poor grounding within the radio (mine had this problem too), but also could be other causes (poor antenna grounding ect.). check out this site for a lot of good information..

Cecil, W6RCA wrote:
"Somewhere I saw a chart of gain VS height of radials.:"

Maybe it was in the August 1988 issue of QST.

Brown, Lewis, and Epstein found that placing radials on the surface of the earth was better than burying them, but it didn`t seem to impair results much to bury them and this was usually more practical, so they`ve been usually buried. In their well known and accepted study, the three pioneers tested, using 3 MHz.

Al Christman, KB8I used NEC-GSD to model a 1/4-wave vertical with 120 buried 1/4-wave radials at depths of 6,4, and 2 inches. (one depth at a time)
3.8 MHz was his test frequency. His results were almost the same for the three depths, improving slightly with shallower burial.

Al repeated the above modeling with 4 radials instead of the 120. It reduced his field strength from 33 to 25 mv/mtr. That doesn`t look like much, but it raised his feedpoint resistance from 40 ohms to 75 ohms.

Al concluded that much of the power radiated by the 120-radial system was wasted heating the soil in the 4-radial system.

Next, Al modeled the 1/4-wave vertical with 4 radials at 5, 10, 15, 20, 25, and 30 feet above the earth.

Al found that maximum radiation at 20 degrees above the horizon came from elevating the antenna and its radials to 10 feet. It declined at greater heights for the radials. But, the height of the radials had to be15 feet to equal the low-angle performance of the buried radial system.

Al has an extensive report in the August 1988 edition of QST where more accurate and detailed information can be found.

Best regards, Richard Harrison, KB5WZI

You are correct. I wasn`t looking ahead. We may need to rely on volunteers for relief of disasters both acute and chronic.

Still think an ounce of prevention and paid professionals are cheaper and better in the long run. But, amateurs had better be ready and able to work as never before.

This is a question I've pondered over the years, as I built amps. I
always wound up shorting the unused turns. There has to be a good reason
why every commercial bandswitching amp you see does it that way.
I just looked in my amplifier manual folder and of the five amplifier
manuals I have, three Heath, two Dentron and an Alpha, every one shorts.

Stan Labinski, Jr. wrote:
"Running separate ground wire from the mast?...naw, the cable`s shield will probably be sufficient---."

You probably should not rely on the coax shield unless it is big rigid stuff.

NEC requires connection of the antenna and electrical service grounds. I would advise a conductor separate from the coax shield for the required interconnection. It should be as direct and straight as possible. I would coil some of the coax into several turns outside the house to impede the lightning via the coax.

When lightning strikes there will be an enormous potential difference between the two ground points, the antenna support ground and the electrical ground. An enormous current will result. It should flow in the ground wire and not the coax.

Best regards, Richard Harrison, KB5WZI

But don't expect them to do it more than a couple of times. If working near the minimum bending radius, the bend needs to be formed around something, hand bending can easily result in kinks.

Gray

The rest is "Hysteresis",
but in this case BH doesn't mean Big Head. ;)

I imagine the difference is down to the permeability of the material used
for the magnetic circuit.
Some of the modern alloys developed for these applications have become quite
clever.
A bit different from Mild Steel, Stalloy, Cast Iron or Tungsten Magnet Steel
of the early days.

> just lower on the higher gain antennas.

They were modeled at 40 ft, which is not too much higher than 1 wl.
There wouldn't be a drastic difference.
The height above ground makes a huge difference in the elevation pattern
and gain also. The max takeoff angle can be deceptive to the
performance. Say you have a 1/4 wl gp at 8ft. The max takeoff is at
about 14 degrees, and just a bit over 1 dbi at this angle. Raise to 32
ft, and the max takeoff is 30 degrees. Bad? Not always. There is also a
lobe at about 10 degrees that is over 2 dbi at that point. So this
antenna would smoke the first one even though the max takeoff angle is
higher. The lower lobe is still higher than the max lobe on the lower
antenna. Most all of these verticals have a very low max takeoff angle
if they are mounted very high in the air in terms of wavelength. A
common 2m 1/4 wl GP at appx 35 ft will have a max takeoff angle of about
3 degrees. This is very good, and explains why a simple 1/4 wl GP is a
good cheap 2m antenna if mounted high up. You might want to try the
eznec demo and try your antennas in that to see what happens. MK

Reg Edwards wrote:
>
> Roy, the topic of conversation is Ladder Line.

Hm. I'd swear you said something about the lossiness of water. I hope you're not saying this thread is closed.

> With flimsy 300-ohm
> junk, where the line provides a gutter for rainwater, anything can
> happen.

I suppose so. But the line I tested was Belden 8230, which has 20 AWG copper covered steel conductors. It's hardly flimsy junk. As it was strung for the test, with frequent twisting, the line didn't hold any appreciable quantity of water.

> But out of curiosity, at what frequency on the 300-ohm line were
> your measurements made ?

21 MHz

> On what length (feet or metres) of 300-ohm line were the
> measurements made ?

100 feet

> What was the total measured dBs of the 300-ohm line ?

Dry, 0.8 dB. After about two weeks of dry weather, a light rain fell, and the loss increased to 3.7 dB. Later, when hard rain fell, loss dropped to 2.4 dB, then slowly to 1.5. I attributed this to the line getting "washed" with clean water.

As a matter of interest, Belden specifies 1.1 dB/100 feet at 100 MHz, which would be 0.5 dB at 21 MHz assuming purely conductor loss.

> What was the percentage increase between dry and soaked ?

"Soaked" wasn't the worst case. Dry, the loss was 17%. Damp, it was 57%. So the loss when damp was 335% of the loss when dry. Or it was 40% greater. Take your pick.

> And, of vital importance, what measurement method was used ?

I connected the twinlead through two 4:1 transformers, the loss of which (0.2 dB each) was measured by putting them back-to-back. The line was running with a 1.5:1 SWR. I used a Bird wattmeter to measure the power into the line+transformer, and the same meter to measure the power out of the line+transformer. Reverse power was subtracted from forward power

to get the net.

The line was suspended by TV standoff insulators above my wooden deck, several feet off the ground and well away from the deck.

> Finally, what is the estimated uncertainty in the measurement of dB
> differences ?

I was operating at about mid-scale with the Bird, and using the same meter for both measurements, so I'd say measured differences were likely to be within a couple of watts. At a power level of about 50 watts, this is a couple of a tenths of a dB.

> Were you able to determine the change in line impedance and
> propagation velocity between wet and dry from your measurements ?
> This would have been of use in distinguishing dielectric loss from
> copper loss.

No, I didn't have the equipment to make those measurements and I didn't try. I had no reason to suspect that getting the line wet would change the conductivity of the copper, especially since it was coated. with polyethylene. Perhaps you can explain how this might happen.

The results of this experiment were published in "Technical Correspondence", QST, February 1982. It won't be long before you could say this phenomenon was known by the ancients!

I'd welcome seeing the results of any measurements you or anyone else has made using better methodology.

This is a common misconception. A patent forbits others from "making, using, or selling" the patented item. You're in violation of a patent even if you make the patented item for your own use.

However, there's also a great deal of misunderstanding about just what a patent covers. Very briefly, it covers only exactly the combination of items in its claims, plus any variations that would be obvious to a person "skilled in the art". I've only seen two of the claimed three Fractenna patents, and you don't need to worry about stepping on them accidentally. One covers fractal patch antennas with certain characteristics, and the other deals mostly with a method for testing them.

Also, readers should note that, in the U.S. at least, a "pending patent" (really a patent application -- there's no guarantee that a patent will actually issue as a result of an application) doesn't "cover" anything, and doesn't prevent anyone from making, using, or selling anything. (I think it's bizarre that Chip/Phil/Fractenna keep waving this claim about. Any patent attorney or even basic book on patent law explains this.) There's no way to find out what an applicant is even trying to patent, since the application isn't public. And even if you could, the chances of the actual patent being for exactly the same combination of characteristics as the application is really fairly slim. If a patent is issued at all.

I can't locate that issue of QST. But I know that the measurements Al did for his doctoral thesis were at 8 MHz, not 3.8. They were also published in a Lawrence Livermore report, and I thought they were the basis for his QST article. I'd appreciate it very much if you'd double check to see if he really reports measurements at 3.8.

There's some evidence that models of elevated radials might not do as well at low frequencies as at higher ones. If that's true, a possible cause might be the programs' assumption of homogeneous ground. If ground is stratified, there's more chance of deviation between reality and model as the frequency lowers and skin depth increases. So good measurements at a lower frequency than 8 MHz would be welcome.

No, no, no....!!!! God Help Us.... First Freddy Kruger, now....

Frackyesssssss.... Baaaaaccccckkkkkk!!!!!

With his twisted and bent wires and assorted gadgets threatening mayhem....

Clearly the "snowbirds" have returned from Fort Lauderdale, where.... they not only don't know how push "chad" out of a voting card, they also can't get their computers to log on to the Internet NG's.

Once back in New England, where some smart UB students are available to help set up Outlook Express again, well.... watch out.

We need help... or else we'll all be sued into oblivion!

Clearly poor Cecil with his magic cat is no match for this.... Maybe that nice youn man Edward Sissor Hands can help to defend us against the evil machinations of the bent wire freak, Edward seemed like a nice young man and he could easily dissmember those twisted wire abominations....

As to the "imaginary" lawyers... well.... with all the lawyers involved in the election debacle from Florida to Washington now free and ready for new action, it seems that Fracky can have access to all he needs.

Enjoy!

Dr. Cohen also confirms that Roy Lewallen is one of the three individuals who is in copyright violation and will be receiving a cease and desist order shortly. The remainder of his above comments are incorrect or not relevant and are misinformed.

Radio amateurs would do well to assume that if something is not theres they should n't use it freely and without permission. If you have questions seek a

good attorney on IP before incorrect and misleading info of others is used and gets you into trouble. There was a lot to learn from the napster debacle.

Ah! does this apply to civilised countries too :?o

A patent is a sure route to plagiarism, the first thing to do if you want to make something in competition with your major rivals in the market is to go and buy the patent specification. Some companies maintain whole departments that do little else than take all newly issued patents in the fields of interest and catalogues them and advises their various researchers of the existence of innovations.

In most cases varying your own companies technological product to perform a similar function and capitalise on a market already opened by the competition is not a difficult matter, certainly the probability of ending up with a marketable product free of legal entanglement is higher than inventing something useful from scratch.

As for the private individual, when did you last have a visit from any authority that wanted to see the patent numbers on any device that you might be using. I suggest that with the present level of investment in policing patents there is no chance of a protective patent ever being worth the paper and time taken to write it.
The best thing that one can do with a new invention is to get it onto the market as quickly as possible before the competition has the chance to catch up. Then be in a position to lead with the next innovation. This requires hiring the right people and treating them properly.

[snip]

Bill, thanks for that feedback. For a manufacturer of "store bought" tuners, I agree with your assertion, it's the "best" thing to do for the potentially "careless" operator.

However, I only partially agree since... especially with a roller or continuously variable inductor, one does not know exactly where those self-resonant -suckout- frequencies are lilely to occur in advance, and when adjusting to "tune" arbitrary unknown impedance transformations, one does not know where the roller will be set.

This then is exactly what manufacturers of "store bought" roller inductor tuners assume and so they simply "short the unused turns". It's safer for them to do that... than to attempt to give the "operators" who buy their widely adjustable equipment instructions sufficient to enable the operators to avoid potentially destructive self-resonances. I believe some manufacturers even describe this technique as "self-resonance killer" or some such terminology.

And so you are correct in your assertion, for most applications of the roller inductor it is simpler for the manufacturer to short the turns and force the operator to take the losses in the shorted turns rather than

taking the chance on a sporadic resonance in unterminated turns causing other kinds of "havoc" such as resonant arcing, burning of contacts, and perhaps destruction of some delicated components, etc.....

However with the situation of a fixed known antenna used on multiple bands which can be set up a priori with a tapped inductor or set of plug in coils with adjustable taps, or at lower freqencies where self resonance is not likely a problem, or with knowledgeable home designers/builders, it's certainly less lossy to leave the unused turns open.

If you know where the self-resonances are, then just... don't go there! If you don't, then be careful.

And... at even lower frequencies one should never short unused turns, for instance on a 60Hz autotransformer. Variac does not short the unused turns on their variable transformers. Short out those turns and see what happens. The stored up smoke will escape from the Variac ruining it forever!

Again, you are correct about shorting the turns and taking the losses in the arbitrary case with a store bought tuner intended to operate on an arbitrary set of unknown impedance transformations. It is simply a waste of power to short turns if you know what you are doing and know how to avoid self-resonances.

Reg: I too read Wes's, write up on wet lines and I congratulate and thank him for his efforts. I believe that his specific measurements were probably accurate and quite adequate for an amateur set up. But I can't really support all of his assertions and conclusions about wet lines as drawn from those specific sets of measurements. I also noted some discussions in his short paper about "conjugate match" which I felt were inappropriate to the point at hand, i.e. another example of using a load theorem for a source problem, etc.... I wonder what "conjugate matching" has to do with wet lines? Wes? -Peter K1PO
